

DESCRIPTION

COMPOSITE POROUS MEMBRANE AND PROCESS FOR  
PRODUCING THE SAME

TECHNICAL FIELD

[0001]

The present invention relates to a composite porous membrane capable of effectively and efficiently separating target substances of micron size, such as various types of bacteria, yeasts, or cells, which has easy handlability in use and membrane strength sufficient for facilitating the processing thereof into various types of filter forms.

In addition, the present invention also relates to a blood filtration membrane, a process for producing a leukocyte-removed suspension causing only a small loss of hemocyte suspension, and a leukocyte removal filter device, which are used when leukocytes are removed from a hemocyte suspension including, as a representative example, whole blood or a blood product used for blood transfusion.

Moreover, the present invention relates to: a cell culture diaphragm, which efficiently allows two or more types of different cell groups to come into contact with one another, while maintaining a state where such different cell groups are not mixed with one another and are kept separated from one another, when

such different cell groups are co-cultured in a culture solution; and a process for culturing cells using a composite porous membrane.

#### BACKGROUND ART

5 [0002]

In a medical field, a bioprocess field, and a regenerative medical field, which use cells, it is important to develop a technique of effectively and efficiently separating such cells. In addition to the 10 centrifugation technique that has conventionally constituted mainstream, the development of a membrane material used for separation directed towards the efficiency of cell separation (reduction in the time required for filtration operations and cost reduction), 15 and the development of a precise cell separation technique using magnetic beads modified with antibodies, have actively been progressing in recent years. Among others, cell separation using a membrane material is considered to be an efficient cell 20 separation technique, and thus such cell separation technique intends to be widely applied in a medical field and a bioprocess field.

For example, in a pharmaceutical manufacturing field, the development of a bioprocess of 25 producing value-added pharmaceutical products such as erythropoietin, human growth hormone, human insulin or interferon has vigorously been progressing, using

animal cells. In addition, in a bioprocess involving a suspended cell culture method for example, various membrane materials are used in a "cell separation process" of separating cells cultured at a large scale  
5 in a fermenter from a medium containing useful components, and also in a "purification process" of isolating such useful components from the separated medium. The cost required for such a cell separation process and a purification process in the  
10 aforementioned bioprocess makes up a major part in the total pharmaceutical manufacturing cost. Thus, the development of efficient cell separation and purification processes is important. Accordingly, it is strongly desired that a filter structure capable of  
15 efficiently avoiding clogging caused by cells, cell-derived components, culture solution-derived components, etc. over the whole process, and a filtration system, be designed.

[0003]

20 In the aforementioned process using a filter, namely, in a process ranging from a cell separation process to a process of purifying useful components, in order to suppress clogging as much as possible, so as to improve cost performance regarding pharmaceutical  
25 manufacturing, first of all, it is important that cells are separated from a medium effectively (the improvement of a cell concentration rate) and efficiently (reduction in filtration time) at the

initial stage. For such purpose, the effectiveness of the use of a suitable pre-filter has been known. Thus, meshes having a pore size suitable for cell separation, high pore size uniformity (a membrane material with 5 high pore size uniformity does not have a small pore size portion that is likely to cause clogging), and high opening ratio, are often used as such pre-filters. Accordingly, it can be said that a filter having a pore size and pore size uniformity necessary for efficiently 10 capturing and separating cells, and high opening ratio that enables rapid filtration, is preferable also in cell separation.

When a filter for separating or removing cells (generally having a size ranging from several 15 microns to several tens of microns) is conceived, if taking into consideration deformation of cells occurring during filtration, a pre-filter having a pore size of several microns, pore size uniformity, and high opening ratio, is mainly preferably used. However, in 20 the case of a polymeric fiber mesh filter that is generally often used as a pre-filter for example, the smallest pore size of such a filter is a square pore with a side of 20  $\mu\text{m}$  or less. Thus, when such a filter is used as a filter for cell separation, cells are 25 dropped out of such pores, and thus it does not function as an effective filter (or pre-filter) in many cases.

On the other hand, some metal mesh filters or polymeric fiber mesh filters produced by special production methods have a pore size of several  $\mu\text{m}$ . In such a case, the diameter of such a metal fiber or 5 polymeric filter cannot be extremely decreased, and as a result, the opening ratio thereof is generally significantly reduced. Moreover, since water permeability is low and the clogging of the filter easily takes place, such a metal mesh filter or 10 polymeric fiber mesh filter cannot be an effective filter used for cell separation or elimination.

As a product having a shape that is not that of a mesh filter, an "etched membrane," which is produced by applying electron beam or ion beam to a 15 thin membrane such as polycarbonate and then subjecting to an etching process, has been broadly known. Such an etched membrane has cylindrical pores with a uniform pore size, and the uniformity of such a pore size is extremely high. However, only several % of opening 20 ratio can be obtained due to the production process thereof. (If opening ratio intended to increase, pore size uniformity would be lost.) When such an etched membrane is used as a separation membrane, the membrane thickness thereof must be at the minimum 10  $\mu\text{m}$  for 25 strength retention (in general, a thickness between 15 and 20  $\mu\text{m}$ ). However, since the pore length becomes greater than the pore size, filtration resistance increases, and thus it cannot be said that filtration

efficiency is sufficient. Moreover, since cylindrical pores produced by such a production method are of straight pore-type, and many of them independently exist, it is extremely rare that pores are connected 5 with one another in a membrane (pores communicate with one another). This is also a factor for low filtration efficiency.

[0005]

Patent Document 1 discloses a porous polymer 10 membrane wherein micro-porous layer (A) and porous layer (B) having straight pore-type pores exist as a laminated structure. This publication describes that porous layer (A) has mechanical strength and that as a result, the thickness of an etched membrane as porous 15 layer (B) can be reduced, such as one with a thickness of 10  $\mu\text{m}$  or less. However, since the opening ratio, porous structure, and internal membrane structure of porous layer (B) are the same as those of the conventional etched membrane, filtration efficiency is 20 not sufficient. Thus, this porous polymer membrane cannot be an efficient separation filter for cells or the like.

In addition, Patent Document 2 discloses a method for producing a porous membrane with controlled 25 pore size, which comprises applying visible ray or far ultraviolet ray to a polymer membrane via a mask and then eliminating the light irradiation region from the polymer membrane. This publication also discloses a

method for forming (integrating) such a porous membrane on (with) a substrate (supporting medium) such as a non-woven fabric or synthetic paper. A porous membrane integrated with a substrate that is obtained by this 5 method has a structure similar to that of the porous polymer membrane disclosed in Patent Document 1. However, since the region in which pores are formed can be controlled with a mask, it becomes possible to set opening ratio at relatively high. Thus, it is 10 anticipated that filtration efficiency is also improved to a certain extent. However, since pores are formed by light irradiation, the pore structure and internal membrane structure thereof are the same as those of an etched membrane. Furthermore, this integration method 15 involves spin-coating a polymer solution on a substrate with a rubber roller, and then drying it, so as to form a porous membrane. Thus, reduction in membrane thickness is difficult, and the polymer solution is likely to penetrate into the supporting medium 20 substrate. As a result, reduction in the thickness of a porous membrane and the uniformity of membrane thickness become difficult, and the structure of a composite membrane is likely to become non-uniform. In particular, this phenomenon significantly takes place 25 when a membrane is formed on a supporting porous substrate having a large average pore size, which has low filtration resistance or on which cells can easily move. Accordingly, a membrane material obtained by

this technique cannot either be an efficient separation filter for cells or the like.

That is to say, a filter material having pores with a pore size of several  $\mu\text{m}$  (for example, approximately 1 to 5  $\mu\text{m}$ ), which has high pore size uniformity and high opening ratio, wherein the pores are short in the direction of a membrane thickness (that is, the membrane thickness is thin), and they are connected with one another in the membrane, and which also has excellent mechanical strength, is useful as an effective and efficient separation filter used for cells or the like (or a pre-filter).

[0006]

Recently, Non-Patent Documents 1 and 2 have described that a micro droplet of water condensed and generated on a polymer solution due to the loss of latent heat during a solvent volatilization process from the polymer solution acts as a template, and that a honeycomb-structured thin porous membrane having through-pores with a pore diameter of several  $\mu\text{m}$  order, which has high pore size uniformity and high opening ratio, can be finally produced using various materials. This thin membrane has almost the same thickness as the diameter of a through-pore, and pores adjacent to each other are connected with each other in the membrane. Thus, this membrane adopts a structure wherein pores communicate with one another in the direction of a membrane flat surface. It is anticipated that a

honeycomb-structured thin porous membrane having such a structure be used as an effective and efficient cell separation filter (or pre-filter).

Such a honeycomb-structured thin porous membrane is produced by casting a solution of an organic polymer in a hydrophobic organic solvent on a smooth solid substrate (for example, a glass, silicon wafer, metal plate, polymer solid gel, etc.), blowing air with high humidity of 40% to 95% thereon, so as to form a honeycomb structure on the substrate, and then peeling it off. However, since the strength of the obtained honeycomb-structured thin porous membrane is generally extremely low, the membrane should be peeled from the solid substrate slowly and carefully.

Otherwise, the membrane is broken. Accordingly, in many cases, it is necessary that a thin membrane have previously been got wet with ethanol or the like, so as to improve peeling properties. That is to say, since the aforementioned production process using a smooth solid substrate is complicated and has poor production stability, it is naturally predicted that it becomes extremely difficult to achieve a continuous membrane formation process or a membrane formation process for realizing high productivity. In addition, in the case of using a smooth solid substrate, if the affinity of a water droplet acting as a template for the solid substrate is insufficient, a honeycomb-structured thin porous membrane has insufficient formation of through-

pore in many cases. If the formation of through-pores is insufficient, it cannot exhibit functions as a filter material.

[0007]

5 Patent Document 3 discloses a method for obtaining a honeycomb-structured thin porous membrane, which comprises casting a hydrophobic organic solvent solution on the water surface to form a honeycomb structure, and then skimming this structure with a  
10 frame of 5 mmφ. With regard to such membrane formation using a water substrate, the formation of through-pores tend to be easy. However, since it is difficult to uniformly cast a solution on the water surface, it is difficult to form a membrane with a large area.  
15 Moreover, depending on materials, wrinkles are generated due to the contraction of a membrane during a process of removing a solvent. Accordingly, it is predicted that it is extremely difficult also for this method to achieve a process for realizing high  
20 productivity.

Furthermore, a honeycomb-structured thin porous membrane material obtained by the aforementioned method has extremely low membrane strength. Thus, when such a membrane material is singly used as a cell  
25 separation filter in a bioprocess field or medical field, it is predicted that membrane break takes place at a high frequency. Further, it is also difficult to process such a membrane into a form other than a flat

membrane, such as a roll-, pleated-, cylindrical, or bag-form, and to use it. That is to say, such a thin membrane material cannot directly constitute a practical filter material, and thus, it is essential to  
5 impart practical mechanical strength to such a membrane material.

A membrane material having pores with a pore diameter of several  $\mu\text{m}$ , which has high pore size uniformity, high opening ratio, and a membrane  
10 structure extremely excellent in terms of filtration efficiency, and which also has practical mechanical strength, is useful as an effective and efficient separation filter (or pre-filter) used for cells or the like. Such a membrane material is particularly useful  
15 for separation of blood cells in a blood filtration field, and more specifically for separation of blood plasma from whole blood or the removal of leukocytes from various blood products.

[0008]

20 In recent years, in order to reduce the physical burden of a patient to which transfusion therapy is applied, the importance of a technique of highly removing leukocytes from a hemocyte suspension including, as typical examples, whole blood and a blood  
25 product used for transfusion (an erythrocyte product, a thrombocyte product, a blood plasma product, etc.) has increased in a medical field.

An example of a method for removing

leukocytes is a filter method, which comprises filtration of a hemocyte suspension, using, as a filter element, a fibrous filter element such as a non-woven fabric, or a porous body having continuous pores in a 5 three-dimensional network state. This filter method is advantageous in that it has high capability of removing leukocytes, in that the operations are simple and easy, and in that it is excellent in terms of cost performance. Thus, at present, the filter method is 10 widely applied in medical sites. A filter used in this method has been known as a "leukocyte removal filter."

Representative examples of such a leukocyte removal filter may include: filters comprising, as a filter element, a non-woven fabric consisting of 15 ultrafine fibers such as polyester, as disclosed in Patent Documents 4 and 5; and filters comprising, as a filter element, a porous body having continuous pores in a three-dimensional network state consisting of polyurethane or the like, as disclosed in Patent 20 Document 6. These publications disclose that the use of such filters achieves 99.99% or more of capability of removing leukocytes.

[0009]

When a hemocyte suspension is filtrated using 25 a leukocyte removal filter, a portion of the hemocyte suspension remains in a filter element after completion of the filtration.. This results in the loss of a precious hemocyte suspension (in particular, in the

case of an expensive blood product). Accordingly, in order to improve the cost performance of users dealing with large quantities of blood products, the need for the development of a product, the volume of a filter element of which is reduced, so as to reduce the loss of a hemocyte suspension, while maintaining the ability of a leukocyte removal filter to remove leukocytes (99.99% or more), has significantly increased under present circumstances.

10       The aforementioned Patent Document 4 discloses a leukocyte removal filter formed by coating the surface of a non-woven fabric used as a filter element with a coating agent containing a nonionic hydrophilic group and a nitrogen-containing basic 15 functional group (for example, a copolymer consisting of 2-hydroxyethyl methacrylate and 2-(N,N-diethylamino)ethyl methacrylate), and then laminating a plurality of the thus coated non-woven fabrics. In this case, it is considered that the removal 20 (capturing) of leukocytes is carried out by adsorption mechanism, and that the nitrogen-containing basic functional group has the effect of selectively adsorbing leukocytes and the nonionic hydrophilic group has the effect of suppressing non-selective adsorption 25 of various blood cell components.

      In order to reduce the volume of a filter element in such a leukocyte removal filter while maintaining its capability of removing leukocytes, it

is considered adequate to increase the content of nitrogen-containing basic functional groups acting as leukocyte-selective affinity functional groups for the purpose of increasing capability of removing leukocytes per unit volume of a coated non-woven fabric. However, as a matter of fact, not only the adsorption ability of leukocytes but also the adsorption ability of other blood cell components (erythrocytes or thrombocytes) is increased by the increase in the quantities of the nitrogen-containing basic functional groups (non-selective adsorption). Consequently, the ability to selectively capture leukocytes is rather decreased. In some serious cases, the clogging of the filter occurs as a result of the adsorption of large quantities of blood cell components. Thus, it cannot be said that an increase in the quantities of nitrogen-containing basic functional groups is effective.

[0010]

Patent Document 7 discloses a method for removing leukocytes from blood using an etched membrane with a pore size between 3 and 10  $\mu\text{m}$ . In addition, Patent Document 8 describes that the honeycomb-structured thin porous membrane described in Non-Patent Documents 1 and 2 is used as a filter element for filtration of human blood, thereby obtaining excellent ability to selectively remove leukocytes.

Interestingly, these results show that using a novel thin porous membrane material having a uniform pore

size of several- $\mu\text{m}$  order, depending on size effect, only leukocytes can be selectively captured from among leukocytes (with a diameter of approximately 15  $\mu\text{m}$ ), erythrocytes (with a diameter of approximately 7  $\mu\text{m}$ ), 5 and thrombocytes (approximately 3  $\mu\text{m}$ ) existing in human blood. Such a filter element becomes a focus of attention also as a novel blood cell separation filter material.

However, when such an etched membrane or 10 honeycomb-structured thin porous membrane is used as a filter element for a leukocyte removal filter, such a membrane enables only superficial capturing of leukocytes on the surface of a thin porous membrane. Thus, in order to capture all leukocytes contained in 15 450  $\text{cm}^3$  of human whole blood for example, without the clogging of a filter, a thin porous membrane with an extremely large area is necessary. Consequently, since the size of a filter must be significantly larger than that of the conventional filter, such a filter is 20 problematic in that (1) workability is significantly decreased in medical sites, (2) a filter holder (or filter housing) becomes significantly large, and the production cost is also significantly increased, and (3) in the formation of a thin porous membrane with a 25 large area, product management (mainly, the management of pinholes or pore size uniformity) is extremely difficult in terms of mechanical strength. Thus, it is difficult to say that this is a practical technique.

[0011]

As stated above, in order to significantly reduce the amount of a hemocyte suspension remaining in a filter element while maintaining the ability of a leukocyte removal filter to remove leukocytes, it is radically necessary to significantly reduce the volume of the filter element. In order to realize such reduction in the volume of filter element, it is essential to develop a leukocyte removal technique of allowing a small filter element to exhibit high capability of removing leukocytes. However, as it has conventionally been studied, it has been difficult to achieve such a technique only by designing the balance of a subtle chemical interaction between each blood cell component and a filter element surface or by optimizing functional groups.

In a medical field and a bioprocess field, in order to achieve a cell culture for allowing various types of useful cells to effectively grow, various techniques regarding the search for a culture solution composition, the design of a scaffolding for effective cell growth, etc., have been developed.

In particular, in recent years, regenerative medicine, in which stem cells having latent ability to differentiate into various types of organs are treated, has become a focus of attention. Regenerative techniques of regenerating several types of organs such as blood vessel, heart muscle, or pancreas, are at a

stage in a process of clinical application. For further development of such regenerative medicine, large quantities of stem cells are necessary for conducting various basal and clinical experiments.

- 5 Thus, at present, in addition to the development of a technique of collecting stem cells from a stem cell source, the development of a technique of allowing the thus collected undifferentiated stem cells to effectively grow in vitro has become a focus of  
10 attention.

[0012]

For example, the effectiveness of regenerative medicine involving transplantation of hematopoietic stem cells has previously been focused in  
15 the treatments of acute myelocytic leukemia or anaplastic anemia, including bone marrow transplantation as a typical example. Currently, the effectiveness of regenerative medicine has become a focus of attention also in vascularization therapy for  
20 patients with the gravest peripheral arteriosclerosis (Buerger's disease, arteriosclerosis obliterans, diabetic gangrene, etc.). Such a vascularization therapy involving transplantation of hematopoietic stem cells has increasingly recognized by the medical  
25 profession. Accordingly, in order to further develop transplantation of hematopoietic stem cells for the treatment of various diseases including the aforementioned diseases in future, it is necessary to

develop a technique of ensuring sufficient quantities of hematopoietic stem cells used for studies or clinical application.

At present, representative examples of a source of hematopoietic stem cells may include bone marrow, peripheral blood, and cord blood. From the viewpoint of noninvasiveness to a donor and reduction in hours on duty during collection of hematopoietic stem cells, at current, transplantation of hematopoietic stem cells derived from cord blood has sharply increased. For example, in April, 2003, the number of transplantation of cord blood-derived hematopoietic stem cells per month (47 cases) has exceeded the number of bone marrow transplantation (46 cases) for the first time.

However, collection of hematopoietic stem cells from a cord blood source is disadvantageous in that the amount collected from a single donor is small. Thus, under the current circumstances, cord blood-derived hematopoietic stem cells are mainly transplanted into a child patient whose body is small. Accordingly, if undifferentiated hematopoietic stem cells collected from the cord blood of a single donor were allowed to grow in vitro, the cells could also be naturally transplanted into adult patients. Thus, it can be said that this becomes an extremely revolutionary technique.

That is to say, it is important for

hematopoietic stem cell transplantation to collect as many hematopoietic stem cells as possible from a single donor and then transplant them. Thus, studies have been vigorously conducted directed towards the 5 effective growth of not only cord blood-derived hematopoietic stem cells, but also peripheral blood- and bone marrow-derived hematopoietic stem cells.

[0013]

Recently, it has been reported that when cord 10 blood-derived hematopoietic stem cells are co-cultured with mouse bone marrow-derived stromal cells in the presence of a certain kind of cytokine, the growth of undifferentiated CD34 positive cells is significantly promoted (Non-Patent Document 3). In this case, the 15 cord blood-derived hematopoietic stem cells are co-cultured with the mouse bone marrow-derived stromal cells in a state where the two types of cells are separated from each other with a polymer diaphragm material. This publication describes that the 20 hematopoietic stem cells are allowed to come into contact with villi extended from the stromal cells via the pores of the polymer diaphragm material, so that the above hematopoietic stem cells can effectively grow while they remain undifferentiated. If such a culture 25 technique of co-culturing hematopoietic stem cells with different cells in a state where the two types of cells are separated with a diaphragm material and allowing the hematopoietic stem cells to grow by intracellular

contact via the pores of the diaphragm were developed, it would facilitate the separation and collection of the grown hematopoietic stem cells. Accordingly, there is a possibility that such co-culture would constitute 5 an extremely practical in vitro hematopoietic stem cell growth method.

As stated above, in order to allow a certain type of useful cells to grow by co-culture with different cells and then easily and efficiently recover 10 such useful cells after the growth, it is effective to use a diaphragm material having a large number of pores. A diaphragm material used for such purpose is required to have the following properties:

(1) the diaphragm material has as large pores 15 as possible within a range where cells do not move through the diaphragm, so as to effectively conduct only intracellular contact;

(2) in order to conduct effective 20 intracellular contact, the diaphragm has high opening ratio;

(3) in order to conduct effective intracellular contact, the diaphragm has a small membrane thickness;

(4) it has high membrane strength that is 25 sufficient for facilitating an operation to recover useful cells after the growth, or the like; and

(5) it can be processed into various membrane forms suitable for effective cell culture.

[0014]

In order to satisfy condition (1) above, membrane materials with high pore size uniformity are first selected. Thereafter, from among such membrane 5 materials with a uniform pore size, a membrane material having the largest average pore size within a range where cells do not move through a diaphragm is preferably selected and used.

As described in the section regarding a cell 10 separation or elimination filter, examples of such a membrane material with high pore size uniformity may include a polymeric fiber mesh, a metal mesh, an etched membrane, and a special thin porous membrane formed using a micro water droplet as a template.

15 A common polymeric fiber mesh has a large pore size. Thus, when such a polymeric fiber mesh is used as a cell culture diaphragm, general cells move through pores. In particular, such a polymeric fiber mesh cannot be used as a diaphragm used for the culture 20 of hematopoietic stem cells having a diameter of approximately 7  $\mu\text{m}$ .

Several metal meshes, or polymeric fiber meshes formed by special production methods, have a pore size of less than 10  $\mu\text{m}$ . However, in general, 25 since such meshes have significantly reduced opening ratio, they do not satisfy condition (2) above. Thus, although such meshes can be used as diaphragms, they do not enable effective intracellular contact.

Accordingly, it cannot be said that such meshes are practical as diaphragm used for the co-culture of cells.

An etched membrane is used as a diaphragm in 5 Non-Patent Document 3. However, the opening ratio of such an etched membrane is low, and thus this membrane cannot satisfy the aforementioned condition (2), as in the case of meshes. Thus, this etched membrane cannot be a practical diaphragm for the co-culture of cells.

10 Although the membrane integrated with the supporting medium of Patent Document 2 satisfies condition (2) to a certain extent, but it is still insufficient. Moreover, since a polymer solution is applied on the supporting medium by spin-coating with a rubber roller,

15 it is difficult to form a thin membrane. Further, since the polymer solution is likely to penetrate into the supporting medium substrate, it is also difficult to form a thin porous membrane and uniformize the membrane thickness. Thus, the structure of a composite

20 membrane is likely to become non-uniform. Hence, since it is difficult to obtain a porous membrane as a uniformly thin membrane, such a porous membrane cannot satisfy the aforementioned condition (3). A membrane material produced by this technique cannot either be a

25 diaphragm for efficient cell culture.

A special thin porous membrane produced using a micro water droplet as a template satisfies the aforementioned conditions (1) to (3). Thus, there is a

possibility that this membrane can be used as a diaphragm material for efficient cell culture. However, since such a membrane has a membrane thickness of several microns, its strength is extremely low, and 5 thus the membrane is easily broken. Accordingly, it is difficult to use a membrane with a large area for the purpose of culturing large quantities of cells or to process such a membrane into various forms (for example, in the form of a bag, roll, or the like) that 10 are suitable for the growth of large quantities of cells or separation and collection of cells of interest. Therefore, such a membrane cannot satisfy the aforementioned conditions (4) and (5), and thus it cannot directly be a practical cell culture diaphragm.

#### DISCLOSURE OF THE INVENTION

##### Problems to be Solved by the Invention

5 [0016]

It is an object of the present invention to provide a membrane material capable of effectively and efficiently separating target substances of micron size (for example, cultured cells or blood cells) based on 10 precise size separation, which has membrane strength sufficient for easy handlability and enables the processing thereof in various types of membrane forms. In addition, it is another object of the present invention to provide a process for producing a 15 leukocyte-removed hemocyte suspension using the above membrane material, which significantly reduces the volume of a filter element while maintaining high capability of removing leukocytes, and which is able to significantly reduce the loss of a hemocyte suspension 20 after filtration operation, and a leukocyte removal filter device.

Moreover, it is another object of the present invention to provide a process for culturing cells using the above membrane material as a cell culture 25 diaphragm used for the co-culture of two or more types of different cell groups in a cell culture solution, which efficiently allows such two or more types of

different cell groups to come into contact with one another, while maintaining a state where such different cell groups are not mixed with one another and are kept separated from one another.

## 5 Means for Solving the Problems

[0017]

As a result of intensive studies directed towards achieving the aforementioned objects, the present inventors have completed the present invention.

10 With regard to the leukocyte removal filter using a non-woven fabric described in the section regarding prior art techniques, the present inventors have analyzed the relationship between the number of such non-woven fabrics and the capability of removing  
15 leukocytes. As a result, the inventors have found that when the number of such non-woven fabrics is small, the capability of removing leukocytes increases as the number of such fabrics increases, but that when the number of non-woven fabrics becomes large, such effects  
20 gradually decrease. The inventors have also found that when the composite porous membrane of the present invention, which has pores with a size capable of selectively capturing leukocytes, having a high size uniformity, and which also has practical mechanical  
25 strength, is used with the combination of a non-woven fabric or a porous body having continuous pores in a three-dimensional network state under specific

conditions, drastic reduction in the volume of a filter element can be realized while maintaining high capability of removing leukocytes, thereby completing the present invention.

5 That is to say, the present invention includes the following (1) to (14):

(1) A composite porous membrane, which comprises at least one porous membrane comprising an organic polymer and at least one supporting porous membrane  
10 adjacent thereto,

wherein the organic polymer constituting the porous membrane penetrates into at least a portion of the surface of the supporting porous membrane adjacent to the porous membrane, and

15 when the membrane flat surface of the porous membrane is observed using a photomicrograph, the porous membrane has an opening ratio between 10% and 90%, an average pore diameter D ( $\mu\text{m}$ ) of  $0.1 \leq D \leq 50$ , a standard deviation  $\sigma d$  ( $\mu\text{m}$ ) of pore diameter of  $0 \leq \sigma d/D \leq 0.6$ , and the percentage of through-pores to all the pores of the porous membrane of 30% or more; when a  
20 membrane section thereof is observed using a photomicrograph, the porous membrane has an average membrane thickness T ( $\mu\text{m}$ ) defined by  $0.05 \leq T/D \leq 2$  and  
25 a structure in which pores adjacent to one another communicate with one another therein; and the supporting porous membrane has continuous pores with an average pore diameter of  $0.5 D$  ( $\mu\text{m}$ ) or more.

(2) The composite membrane according (1) above, wherein the porous membrane has an average membrane thickness  $T$  ( $\mu\text{m}$ ) of  $0.1 \leq T \leq 50$ , and the supporting porous membrane has an average pore diameter of  $1 \mu\text{m}$  or 5 more.

(3) The composite membrane according to (1) or (2) above, wherein the porous membrane has an average pore diameter  $D$  ( $\mu\text{m}$ ) of  $0.1 \leq D \leq 20$  and an average membrane thickness  $T$  ( $\mu\text{m}$ ) of  $0.1 \leq T \leq 20$ , and the 10 supporting porous membrane has an average pore diameter between  $1$  and  $100 \mu\text{m}$  and wherein a standard deviation  $\sigma_T$  ( $\mu\text{m}$ ) of the membrane thickness is defined by  $0 \leq \sigma_T/T \leq 0.5$ .

(4) The composite porous membrane according to 15 any one of (1) to (3) above, wherein the porous membrane has an opening ratio between  $15\%$  and  $80\%$  and an average pore diameter  $D$  ( $\mu\text{m}$ ) of  $0.5 \leq D \leq 20$ .

(5) A blood filtration membrane comprising the composite porous membrane according to any one of (1) 20 to (4) above.

(6) A cell culture diaphragm comprising the composite porous membrane according to any one of (1) to (4) above, which partitions different cell groups in a cell culture solution so that the different cell 25 groups come into contact with each other, and which is used for co-culture of the cells.

(7) A process for producing the composite porous membrane according to any one of claims (1) to (4),

which comprises steps of: allowing a supporting porous membrane to retain a liquid that is not compatible with a solution of an organic polymer in a hydrophobic organic solvent; casting the solution of the organic 5 polymer in the hydrophobic organic solvent on the supporting porous membrane; and evaporating the hydrophobic organic solvent in an environment wherein a relative humidity is between 20% and 100% near the membrane, so as to form a porous membrane containing 10 the above described organic polymer as a main component on the supporting porous membrane.

(8) The process according to (7) above, wherein the liquid that is not compatible with the solution of the organic polymer in the hydrophobic organic solvent 15 is water.

(9) A process for producing a hemocyte suspension from which leukocytes have been removed, which comprises: passing a hemocyte suspension to be treated through a first filter with a capability of removing 20 leukocytes between 1.0 and 3.5 for 450 cm<sup>3</sup> of the hemocyte suspension to be treated; and then passing the whole hemocyte suspension discharged from the first filter through a second filter comprising one or more composite porous membranes according to any one of (1) 25 to (4) above.

(10) A leukocyte removal filter device comprising a first filter disposed on the entrance side of the hemocyte suspension to be treated and a second filter

disposed on the exit side thereof, wherein the first filter has a capability of removing leukocytes between 1.0 and 3.5 for 450 cm<sup>3</sup> of the hemocyte suspension to be treated, and the second filter comprises one or more

5 composite porous membranes according to any one of (1) to (4) above.

(11) The leukocyte removal filter device according to (10) above, wherein the effective area of the second filter is between 4 and 300 cm<sup>2</sup>.

10 (12) The leukocyte removal filter device according to (10) or (11) above, which has a filter element with a volume between 2 and 18 cm<sup>3</sup>.

(13) The leukocyte removal filter device according to any one of (10) to (12) above, which has a

15 capability of removing leukocytes of 4.0 or more for 450 cm<sup>3</sup> of the hemocayte suspension to be treated.

(14) A process for culturing cells, which comprises: disposing the composite porous membrane according to any one of (1) to (4) above in a cell

20 culture solution to establish at least two culture regions; introducing different cell groups into the at least two culture regions adjacent to each other, respectively, and co-culturing the cells.

#### Effects of the Invention

25 [0018]

The composite porous membrane of the present invention comprises a porous membrane and a supporting

porous membrane. Such a porous membrane that controls size separation has a pore size of micron order, high pore size uniformity, and high opening ratio. The thickness of such a porous membrane is thin, and it has 5 high uniformity. The inside of the porous membrane has a structure causing low filtration resistance. In addition, since a supporting porous membrane imparts sufficient mechanical strength, the composite porous membrane of the present invention brings on easy 10 handability in use, and thus it can be processed into various types of membrane forms. As a result, the use of the composite porous membrane of the present invention enables effective and efficient precise size filtration of various types of cells. Moreover, a 15 leukocyte removal filter device using the present composite porous membrane enables significant reduction in the volume of a filter element while maintaining high capability of removing leukocytes. Thus, this device enables drastic reduction in the loss of a 20 hemocyte suspension (whole blood, an erythrocyte product, a thrombocyte product, a blood plasma product, etc.) caused by the volume of filter element during filtration, and cost performance regarding blood products is thereby drastically improved in medical 25 sites.

Furthermore, the use of the composite porous membrane of the present invention as a cell culture diaphragm enables effective intracellular contact with

different cells via a thin uniform porous membrane, while maintaining a state where different cell groups are not mixed with one another and are kept separated in a cell culture solution. Accordingly, effective  
5 growth of cells of interest (for example, the growth in number of cells in a state where differentiation thereof is suppressed) can be achieved by contact with different cells. Further, since the supporting porous membrane imparts sufficient mechanical strength, the  
10 use of such a composite porous membrane with a large area suitable for practical cell growth, or processing thereof into various types of membrane forms, can be easily achieved. As a result, this composite porous membrane enables the growth of cells of interest in  
15 high volume and easy separation operation after the growth thereof.

#### BEST MODE FOR CARRYING OUT THE INVENTION

[0019]

The present invention will be described in detail below.

The composite porous membrane of the present invention comprises at least one porous membrane containing an organic polymer and at least one supporting porous membrane adjacent thereto.

The composite porous membrane may have a structure wherein a porous membrane is adjacent to and also adheres to a supporting porous membrane (a structure wherein a porous membrane penetrates into a supporting porous membrane). Examples of such a structure may include: a bilaminar structure formed by integrating a single porous membrane with a single supporting porous membrane (that is, a structure consisting of "porous membrane/supporting porous membrane"); a trilaminar sandwich structure wherein porous membranes are located on both sides of a supporting porous membrane (that is, a structure

consisting of "porous membrane/supporting porous membrane/porous membrane"); a trilaminar sandwich structure wherein supporting porous membranes are located on both sides of a porous membrane (that is, a  
5 structure consisting of "supporting porous membrane/porous membrane/supporting porous membrane"); and a trilaminar structure wherein two porous membrane layers are present on either one side of a supporting porous membrane (that is, a structure consisting of  
10 "porous membrane/porous membrane/supporting porous membrane"). A bilaminar structure formed by integrating a single porous membrane with a single supporting porous membrane (that is, a structure consisting of "porous membrane/supporting porous membrane") is preferable because it is easily produced.  
15 [0020]

First, the porous membrane containing an organic polymer (which is not a supporting membrane) of a composite porous membrane will be described.

20 When a pore of the porous membrane is observed from a direction vertical to the porous membrane flat surface, the pore has a round shape, unless external force is given (for example, pulling the composite porous membrane itself in a uniaxial  
25 direction). Depending on the composition of a hydrophobic organic solvent solution or production conditions (for example, the level of gas blowing), the shape of the pore may be somewhat deformed and may have

an elliptical shape. The round shape defined in the present invention includes such an elliptical shape as well as a completely round shape.

When the porous membrane flat surface is observed with a photomicrograph, the porous membrane has an opening ratio between 10% and 90%, an average pore diameter  $D$  ( $\mu\text{m}$ ) of  $0.1 \leq D \leq 50$ , and a standard deviation of pore diameter  $\sigma_d$  ( $\mu\text{m}$ ) of  $0 \leq \sigma_d/D \leq 0.6$ . The percentage of through-pores to all pores of the porous membrane is 30% or more. When the membrane section thereof is observed with a photomicrograph, the porous membrane has an average membrane thickness  $T$  ( $\mu\text{m}$ ) of  $0.05 \leq T/D \leq 2$ . The porous membrane adopts a structure whereby pores communicate with pores adjacent thereto in the porous membrane. Membranes, whose opening ratio,  $D$ ,  $\sigma_d$ , the percentage of through-pores,  $T$ , and internal membrane structure can not be experimentally determined, are excluded from the porous membrane of the present invention. For example, in the case of a non-woven fabric that is preferably used as a supporting porous membrane or a porous body having continuous pores in a three-dimensional network state that is mainly obtained by the phase separation method, it is difficult to determine the aforementioned factors by the methods described in examples. Accordingly, these products clearly differ from the porous membrane of the present invention.

The plane of the porous membrane has an

opening ratio between 10% and 90%, preferably between 15% and 80%, more preferably between 20% and 70%, and most preferably between 25% and 60%. If such an opening ratio is less than 10%, a filtration rate may 5 become slow, or contact efficiency between different cells separated from each other may decrease. In contrast, if such an opening ratio exceeds 90%, the strength of the porous membrane is significantly reduced, thereby causing membrane break or the like.

10 The value of an average pore diameter  $D$  ( $\mu\text{m}$ ) is  $0.1 \leq D \leq 50$ , preferably  $0.1 \leq D \leq 20$ , more preferably  $0.5 \leq D \leq 20$ , and most preferably  $0.8 \leq D \leq 10$ . If the value of  $D$  exceeds  $50 \mu\text{m}$ , it becomes difficult to separate ordinary cells of micron size or 15 the like, and further, it may be difficult to effectively separate different cells from each other. In contrast, if the value of  $D$  is smaller than  $0.1 \mu\text{m}$ , pores are too small to efficiently separate cells in a short filtration time, and further there are some cases 20 where the contact efficiency between different cells separated from each other may decrease.

The standard deviation of pore diameter  $\sigma d$  ( $\mu\text{m}$ ) is  $0 \leq \sigma d/D \leq 0.6$ , preferably  $0 \leq \sigma d/D \leq 0.5$ , more preferably  $0 \leq \sigma d/D \leq 0.4$ , and most preferably  $0 \leq \sigma d/D \leq 0.3$ . If the value of  $\sigma d/D$  exceeds 0.6, the size of a 25 pore diameter becomes widely distributed, and it becomes insufficient to efficiently separate target substances to be separated. In addition, it results in

insufficient precise size separation performance.

[0021]

The composite porous membrane of the present invention is characterized in that an organic polymer constituting the porous membrane penetrates into a supporting porous membrane at least in a part of the supporting porous membrane flat surface adjacent to the porous membrane. For example, when the supporting porous membrane constituting the composite porous membrane is a non-woven fabric, if the surface of the porous membrane in the composite porous membrane is observed under an electron microscope, a state (clogging pore structure) where the shape of a pore is distorted or such a pore is occluded on the back side of the porous membrane (supporting porous membrane side) can be seen as a result of the porous membrane penetrating into a part of the non-woven fabric plane (a fibrous portion or an entangled fiber portion).

That is to say, in the composite porous membrane of the present invention, since the organic polymer constituting the porous membrane penetrates into a part of the supporting porous membrane, such a part of the supporting porous membrane (which is, for example, fibers constituting a non-woven fabric) decreases the through-pore percentage of the porous membrane and occludes pores (such a state is shown in Figs. 1 and 2). As a result, it is extremely rare that all the pores of the porous membrane are through-pores.

In the composite porous membrane of the present invention, the percentage of through-pores in the porous membrane is 30% or more, preferably 40% or more, more preferably 50% or more, and most preferably 5 60% or more. If the ratio of such through-pores is less than 30%, not only a filtration rate or the contact efficiency between different cells separated from each other decreases, but also targets generally passing through such through-pores remain incorporated 10 into clogging pores and captured therein. Thereby, the size separation effect decreases. It is to be noted that the percentage of through-pores in the porous membrane is also affected by membrane formation conditions (for example, the concentration of a 15 hydrophobic organic solvent solution to be casted, the amount casted, the type of a solvent, etc.).

[0022]

In the present invention, the term "through-pores" of the porous membrane is used to mean that when 20 any given pore P is focused in the porous membrane, if the area of the pore P that is actually measured in the electron photomicrograph of the porous membrane flat surface (for example, when the shape of a pore is round, the value of  $(D/2)^2\pi$  calculated from the diameter 25 D of the pore) is defined as S(P), the area of a region (so-called through region) wherein the structure of the supporting porous membrane located on the other side can be observed through the pore P makes up 70% or more

of S(P).

In the present invention, the term "percentage of through-pores" is used to mean the percentage of through-pores to all pores that can be observed in the electron photomicrograph of the porous membrane flat surface. For example, the expression "the penetrating rate of pores is 50%" is used to mean that when there are 10 pores, 5 pores of them are "through-pores."

The average membrane thickness  $T$  ( $\mu\text{m}$ ) of the porous membrane can be measured by observing the section of the composite porous membrane under a microscope (mainly, an electron microscope). The value is  $0.05 \leq T/D \leq 2$ . It is preferably  $0.1 \leq T \leq 50$ , more preferably  $0.1 \leq T \leq 20$ , further more preferably  $0.5 \leq T \leq 20$ , and most preferably  $0.8 \leq T \leq 10$ . If the value of  $T$  is less than 0.1, the strength of the porous membrane decreases, and it is likely to become a cause of membrane break during filtration. In contrast, if the value of  $T$  exceeds 50, it becomes difficult for different cells separated from each other to come into contact with each other. In addition, since the membrane thickness correlates with average pore diameter  $D$ , the pore size necessarily increases, and thus it becomes difficult to separate ordinary cells of micron size or the like.

The standard deviation  $\sigma_t$  ( $\mu\text{m}$ ) of membrane thickness is  $0 \leq \sigma_t/T \leq 0.5$ , preferably  $0 \leq \sigma_t/T \leq 0.4$ ,

and more preferably  $0 \leq \sigma t/T \leq 0.3$ . If the value of  $\sigma t/T$  exceeds 0.5, it results in a wide distribution of membrane thickness, and contact between different cells separated from each other becomes partially difficult.

- 5 Thus, effective contact becomes difficult in some cases.

[0023]

The pores of the porous membrane are characterized in that they communicate with pores adjacent thereto in the membrane. For example, the structure of a porous membrane section is preferably an internal spherical structure as shown in Fig. 4 (an inwardly swollen structure). As a result, since pores communicate with pores adjacent thereto (spherical through-pore 1), when compared with an independent cylindrical structure such as an etched membrane, the filtration resistance of a fluid significantly decreases in the porous membrane, thereby obtaining high filtration efficiency. In addition, even in a case where a part of the supporting porous membrane inhibits through-pore percentage when the above membrane is integrated with the supporting porous membrane, since pores communicate with one another in the direction of the membrane flat surface, even pores whose formation of through-pore is inhibited by the supporting porous membrane are able to contribute to filtration. It is not necessary that all the pores of the porous membrane be communicated with pores adjacent

thereto in the membrane. However, as such a communicated space increases, the filtration resistance of a fluid favorably decreases. Such a communicated structure can be seen by observing the section of a 5 composite porous membrane under a microscope (mainly, an electron microscope), as in the case of membrane thickness.

A process for producing such a membrane structure is not particularly limited. However, since 10 a portion in which pores communicate with pores adjacent thereto can be often seen in a porous membrane produced by a membrane formation method using a water droplet as a template, as described later, such a membrane formation technique can be preferably used for 15 production of the composite porous membrane of the present invention.

The type of an organic polymer forming the porous membrane is not limited, as long as it is dissolved in a hydrophobic organic solvent used. 20 Examples of such an organic polymer may include: single materials including polyesters such as polylactic acid, polyhydroxyacetic acid, polycaprolactone or polyethylene adipate, polyurethanes, poly(meth)acrylic esters, polyvinyl acetals, polyamides, polystyrenes, 25 polysulfones, cellulose derivatives, polyphenylene ethers, and polycarbonates; a polymer alloy or a blend consisting of two or more types selected from among the above substances; and a copolymer consisting of

monomers forming the aforementioned polymer. However, the examples are not limited thereto.

[0024]

Next, a supporting porous membrane will be  
5 described.

When a composite porous membrane is used as a filtration membrane, such a supporting porous membrane has functions to support and reinforce the porous membrane and to impart sufficient mechanical strength  
10 to the composite porous membrane, without impairing the filtration rate. Accordingly, it is preferable that an average pore size be large. In addition, when a composite porous membrane is used as a cell culture diaphragm, the supporting porous membrane has  
15 mechanical strength and, in some cases, also has the function as a scaffolding for cultured cells. In addition, in order to enable intracellular contact via the porous membrane, it is preferable that the supporting porous membrane has a pore size sufficient  
20 for cells to move therein. Accordingly, the supporting porous membrane has continuous pores with an average pore size of 0.5 D ( $\mu\text{m}$ ) or more, preferably 1  $\mu\text{m}$  or more, and more preferably between 1 and 100  $\mu\text{m}$ . If such an average pore size is less than 0.5 D ( $\mu\text{m}$ ),  
25 there are cases where an efficient filtration rate is hardly obtained or where it becomes difficult for cells to move and thus effective intracellular contact through the porous membrane becomes difficult. In

contrast, such an average pore size exceeds 100  $\mu\text{m}$ , there are cases where the supportability of the supporting porous membrane decreases because of decrease in adhesiveness of the porous membrane to the 5 supporting porous membrane.

Such an "average pore size" is a value measured in accordance with the bubble point method described in ASTM-F316-86, using a Palm Porometer (manufactured by Porous Materials, Inc.).

10 The term "continuous pores" is used to mean pores communicated from one membrane flat surface of a supporting porous membrane to the other membrane flat surface on the opposite side. The shape of a pore on the membrane surface or the internal membrane structure 15 thereof is not particularly limited, as long as a liquid or gas passes through such continuous pores.

If the thickness of the supporting porous membrane constituting the composite porous membrane is too large, processability into various filter forms 20 decreases. In addition, there are some cases where the filtration rate significantly decreases or where the mobility of cells decreases. Thus, the membrane thickness is preferably 5 mm or less, more preferably 3 mm or less, and most preferably 1 mm or less. If the 25 supporting porous membrane is too thin, it cannot play a role as a supporting layer in some cases.

Accordingly, the thickness of the supporting porous membrane is preferably 1  $\mu\text{m}$  or more, more preferably 5

μm or more, and most preferably 10 μm or more.

[0025]

Specific examples of such a supporting porous membrane may include: non-woven fabrics obtained from 5 natural fibers, synthetic polymer fibers, regenerative polymer fibers, inorganic fibers including a glass fiber as a typical example, organic/inorganic composite fibers, or the like; and porous bodies (porous membranes) having three-dimensional network continuous 10 pores, which are obtained from organic polymer materials that are fused by heating, dissolved in a solvent in the form of a solution, or plasticized using a plasticizer, according to the foaming method, the phase separation method (thermotropic phase separation 15 method or wet phase separation method), the drawing method, the sintering method, or the like. Further examples may include: woven fabrics or kitted fabrics obtained from natural fibers, synthetic polymer fibers, regenerative polymer fibers, glass fibers, 20 organic/inorganic composite fibers, etc.; and various types of meshes consisting of an organic material, an inorganic material, a metal material, or a hybrid material thereof.

Examples of an organic polymer material used 25 for the supporting porous membrane may include polyalkylene terephthalates, polycarbonates, polyurethanes, poly(meth)acrylic esters, polyacrylonitrile, polyvinyl alcohol, polyvinyl acetal,

polyesters, polyamides, polystyrene, polysulfones, cellulose and cellulose derivatives, polyphenylene ethers, polyethylene, polypropylene, polyvinyl fluoride, polyvinyl chloride, polyvinylidene fluoride,  
5 and a copolymer consisting of monomers constituting these substances, and an alloy and a blend consisting of one or more types of the aforementioned polymers.  
However, the material of the supporting porous membrane of the present invention is not limited to the  
10 aforementioned examples.

Preferred examples of such a supporting porous membrane may include non-woven fabrics, woven fabrics, and meshes. Examples of an organic polymer material forming fibers constituting the supporting  
15 porous membrane may include polyethylene terephthalate, polypropylene, a cellulose derivative, polyamide, and polyacrylonitrile. Of these, polyethylene terephthalate is particularly preferable.

[0026]

20 When the supporting porous membrane is not especially actively allowed to exhibit separation performance, in order to increase the filtration efficiency of a target solution to be filtrated, the supporting porous membrane preferably comprises crude  
25 continuous pores with low filtration resistance and has appropriate strength. Specific examples of such a supporting porous membrane may include a non-woven fabric, woven-fabric, mesh filters, obtained from

organic polymer fibers. Of these, a non-woven fabric is preferable.

When such a non-woven fabric is used as a supporting porous membrane, if the fiber diameter thereof is too large, there are cases where the through-pore percentage of the porous membrane is inhibited, or where increased unevenness of a plane adhering to the porous membrane inhibits the smoothness or thickness uniformity of the porous membrane. In contrast, if the fiber diameter is too small, a portion adhering to the porous membrane decreases. Thereby, in some cases, the supporting porous membrane cannot sufficiently support or reinforce the porous membrane, or it cannot achieve strength sufficient as a composite porous membrane due to a decrease in the strength of the supporting porous membrane itself. Accordingly, the fiber diameter of a non-woven fabric is preferably between 0.1 and 50  $\mu\text{m}$ , more preferably between 0.1 and 30  $\mu\text{m}$ , further more preferably between 0.5 and 15  $\mu\text{m}$ , and most preferably between 0.5 and 5  $\mu\text{m}$ .

Moreover, if a non-woven fabric has too large a mass per unit area, there may be cases where it may inhibit the formation of through-pore of the porous membrane, where the filtration rate decreases, or where it becomes difficult for cells to move. On the other hand, if its mass per unit area is too small, there may be cases where the support or reinforcement of the porous membrane becomes insufficient, or where it

cannot achieve strength sufficient as a composite porous membrane. Accordingly, when a non-woven fabric has a thickness of 200  $\mu\text{m}$  for example, the mass per unit area thereof is preferably between 10 and 200  $\text{g}/\text{m}^2$ ,  
5 more preferably between 15 and 150  $\text{g}/\text{m}^2$ , and further more preferably between 20 and 100  $\text{g}/\text{m}^2$ .

When the supporting porous membrane is actively allowed to exhibit separation performance, for example, when the supporting porous membrane is applied  
10 to a filtration system wherein a solution to be filtrated is first passed through the supporting porous membrane and it is then separated by the porous membrane, the supporting porous membrane is allowed to exhibit the effect as a pre-filter of separating or  
15 adsorbing particles greater than those separated by the porous membrane, thereby preventing the porous membrane from being clogged or increasing the separation efficiency.

The composite porous membrane of the present invention is formed by integrating a porous membrane with a supporting porous membrane. An organic polymer constituting the porous membrane penetrates into at least a portion of the surface of the supporting porous membrane adjacent to the porous membrane, so that a  
25 structure wherein the two membranes adhere to each other can be formed. The presence of such a structure can be confirmed by observing the porous membrane under an electron microscope. The presence of such a

structure enables high adhesiveness between the porous membrane and the supporting porous membrane.

Furthermore, the composite porous membrane may also have a structure wherein both lateral faces of 5 the supporting porous membrane are sandwiched with the porous membranes. In such a case, the average pore diameter, opening ratio, or substances constituting both porous membranes may be identical to or different from each other.

10 If the thickness of the composite porous membrane of the present invention is too thick, processing properties for processing into various types of forms decreases, and the filtration rate may further decrease. Thus, the membrane thickness is preferably 5 mm or less, more preferably 3 mm or less, and most preferably 1 mm or less. On the other hand, if such a thickness is too thin, handability or processability decreases. Thus, the membrane thickness is preferably 1  $\mu\text{m}$  or more, more preferably 5  $\mu\text{m}$  or more, and most 15 preferably 10  $\mu\text{m}$  or more.  
20

[0027]

Since the composite porous membrane of the present invention has strength sufficient for processing, the plane membrane form may also be 25 processed into various types of forms such as a hollow, a bag, or a pleated form. For example, two slices of composite porous membranes with a square form of the same size are laminated such that a supporting porous

membrane (for example, a non-woven fabric) is disposed inward, and the 3 sides thereof are then sealed by heat sealing, thereby obtaining a bag-form sheet, wherein the non-woven fabric exists therein and the entire 5 periphery is covered with the porous membrane.

Furthermore, a single composite porous membrane cut into the form of a sector is rounded, and two chords are then sealed by heat sealing, so as to obtain a funnel structure (conical structure). A rectangular 10 composite porous membrane is rounded, and the attached two sides are then sealed by heat sealing, so as to obtain a tubular form (hollow form). This product can be used for various purposes.

Further, the composite porous membrane can 15 also be processed into a state where it is integrated with another member. For example, the composite porous membrane is allowed to adhere to the end face of a tube made from a glass or plastic by adhesion or fusion adhesion using an adhesive agent, so as to integrate 20 the composite porous membrane with the tube. If the composite porous membrane is allowed to adhere to the end face of a tube, it can be processed into a cup-type container. Otherwise, the composite porous membrane is allowed to adhere to both ends, so as to produce a 25 sealed container.

The composite porous membrane may be used singly (one slice). Several composite porous membranes may be laminated, so as to construct various types of

laminar structures and used them. Still further, by overlaying one or more composite porous membranes on one or more supporting porous membranes constituting them (by combining one or more composite porous 5 membranes with one or more supporting porous membranes constituting them), it becomes possible to provide membrane materials with various performances.

[0028]

Next, a process for producing the composite 10 porous membrane of the invention of the present application will be described.

Processes for integrating a porous membrane with a supporting porous membrane include: (1) a process comprising preparing a porous membrane and a 15 supporting porous membrane separately and then allowing the porous membrane to adhere to the supporting porous membrane; and (2) a process comprising forming a porous membrane on a supporting porous membrane and then simultaneously conducting adhesion and formation of a 20 membrane. The method described in (2) above enables production of a composite porous membrane that has been simply integrated without decreasing strength or permeation rate.

The process for producing the composite 25 porous membrane of the present invention comprises 3 processes of: (a) allowing a supporting porous membrane to retain a liquid that is not compatible with a solution of an organic polymer in a hydrophobic organic

solvent; (b) casting the solution of the organic polymer in the hydrophobic organic solvent on the supporting porous membrane; and (c) evaporating the hydrophobic organic solvent in an environment wherein a  
5 relative humidity is between 20% and 100% near the liquid face, so as to form a porous membrane containing the above described organic polymer as a main component on the supporting porous membrane.

[0029]

10       The expression "solution of an organic polymer in a hydrophobic organic solvent" is used in the present invention to mean a solution obtained by dissolving in a hydrophobic organic solvent, an organic polymer used as a main component of a porous membrane  
15 formed on a supporting porous membrane. The concentration of such a solution is preferably between 0.01 and 30 wt %, more preferably between 0.03 and 15 wt %, and most preferably between 0.04 and 5 wt %. If the concentration is less than 0.01 wt %, there are  
20 cases where the pore regularity of the porous membrane decreases or where membrane strength decreases. On the other hand, if the concentration exceeds 30 wt %, there are cases where a regular honeycomb structure is hardly formed. In addition, in order to form through-pores,  
25 the amount of the "solution of an organic polymer in a hydrophobic organic solvent" casted on the supporting porous membrane must be significantly reduced, so as to decrease the membrane thickness. This causes extremely

high difficulty in membrane formation techniques, and thus it is not favorable.

The type of such a "hydrophobic organic solvent" is not limited, as long as it is an organic solvent that is not compatible (homogenized) with water at any given ratio, in which an organic polymer forming a porous membrane is dissolved. However, since such a solvent is evaporated at a relative humidity between 20% and 100%, a hydrophobic solvent with high volatility, which makes evaporation and elimination relatively easy, is preferably used. Examples of such a solvent may include: halogen organic solvents including chlorides or fluorides such as chloroform, dichloromethane, or dichloroethane; hydrocarbon solvents such as benzene, toluene, xylene, n-hexane, cyclohexane, methylcyclohexane, or decalin; ester solvents such as ethyl acetate or butyl acetate; and water-insoluble ketone solvents such as methyl isobutyl ketone. These solvents are used singly or in the form of a mixture consisting of two or more types. Of these, chloroform, dichloromethane, and toluene are preferable. In particular, chloroform and dichloromethane are more preferable because many types of organic polymers can be dissolved therein and evaporation and elimination is easily conducted. However, when chloroform or dichloromethane is used, since the specific gravity thereof is considerably greater than that (specific gravity 1) of a micro water

droplet used as a template for pores, there are cases where the porous membrane hardly has through-pore form. In such a case, a different solvent capable of adjusting the specific gravity of a solution, such as 5 toluene, may previously be added to chloroform at an amount between 1% and 20% by weight. Such an addition is effective for formation of through-pores.

[0030]

According to the present invention, first,  
10 (a) a supporting porous membrane is allowed to retain a liquid that is not compatible with a solution of an organic polymer in a hydrophobic organic solvent. When such a hydrophobic organic solvent solution is casted on the supporting porous membrane, it is necessary that  
15 the hydrophobic organic solvent solution does not penetrate into the pores of the supporting porous membrane and occlude them. As a method of achieving this, a liquid that is not compatible with the hydrophobic organic solvent solution has previously  
20 been retained by the supporting porous membrane, and the internal pores of the supporting porous membrane are thereby filled with the above liquid. In particular, in the case of using a supporting porous membrane having crude continuous pores, which is  
25 preferable as the supporting porous membrane of the present invention (for example, a non-woven fabric or woven-fabric), the above method is effective for prevention of easy permeation of a hydrophobic organic

solvent solution casted on the supporting porous membrane. Since penetration of the hydrophobic organic solvent solution into the supporting porous membrane is prevented, the solution can be thinly and smoothly 5 casted on the supporting porous membrane. As a result, the porous membrane can be thinly, uniformly, and smoothly formed on the supporting porous membrane, and ultimately, an organic polymer does not occlude the supporting porous membrane.

10 [0031]

The term "liquid that is not compatible with a hydrophobic organic solvent solution" (hereinafter referred to as "incompatible liquid" at times) is used to mean a liquid, which does not become a homogeneous 15 solution when it is mixed with the above solution at a certain amount, and in which almost no organic polymer as a main component of the porous membrane is dissolved. Such an incompatible liquid is not limited but is selected depending on the type of a hydrophobic 20 organic solvent used. An incompatible liquid that can be easily eliminated from the inside of the supporting porous membrane by drying or washing after formation of the porous membrane is preferable.

When the affinity for a water droplet as a 25 template is high, the porous membrane easily forms through-pores. Thus, preferred examples of the aforementioned incompatible liquid may include water, an aqueous solution containing various types of salts

such as sodium chloride, a water-soluble liquid polymer such as polyethylene glycol, and an aqueous solution containing them.

In order to treat such an incompatible liquid  
5 in the industrial field, those having a simple composition are preferable. Among others, water is particularly preferable. It is required for such an incompatible liquid not to dissolve an organic polymer. However, when a hydrophobic organic solvent solution is  
10 allowed to come into contact with the above liquid during formation of the membrane, if an organic polymer contained in the hydrophobic organic solvent solution does not substantially move to the above liquid, the above liquid may dissolve a small extent of such an  
15 organic polymer.

As a method for allowing the supporting porous membrane to retain a liquid that is not incompatible with the hydrophobic organic solvent solution, the supporting porous membrane has been  
20 sufficiently immersed in this liquid in advance, and it is then removed from the liquid and used. (If ultrasonic wave is applied during such immersion, the above liquid can be more effectively retained in the supporting porous membrane.) Otherwise, before the  
25 casting of the hydrophobic organic solvent solution, the above liquid may be directly dropped onto the supporting porous membrane, or may be sufficiently sprayed to the supporting porous membrane.

[0032]

Thereafter, (b) the solution of the organic polymer in the hydrophobic organic solvent is casted on the supporting porous membrane. As a casting method, 5 any method can be applied, as long as it comprises uniformly and completely casting the above solution on the supporting porous membrane. Thus, such a method is not particularly limited. When the viscosity of the solution is low, it is directly casted on the 10 supporting porous membrane. When the viscosity is high, it is uniformly casted using a blade coater or the like.

For the purpose of improving the membrane formation stability or strength of the porous membrane, 15 modifying the surface thereof (for example, imparting hydrophilicity thereto), or imparting toughness thereto, other additives may be added, as long as they are substances that can be dissolved in the hydrophobic organic solvent solution used in the present invention. 20 For example, when one or more types of amphipathic compounds, such as bis(hexadecyl) ammonium bromide described in Mater. Sci. Eng., Vol. C8-9, p. 495 (1999), are added, the membrane formation stability, pore size, and pore shape uniformity of the porous 25 membrane preferably increase. In particular, a polyacrylamide amphipathic compound represented by the following structural formula (I) is a preferable example.

[0033]

[Formula 1]

[0034]

When the aforementioned amphipathic compound  
 5 is added to the hydrophobic organic solvent solution,  
 the composition ratio between the organic polymer and  
 the amphipathic compound (organic polymer/amphipathic  
 compound (wt/wt)) is not limited. It is preferably  
 between 99/1 and 50/50 (wt/wt). If the ratio of the  
 10 amphipathic compound is smaller than 99/1, a uniform  
 porous membrane is hardly formed. If the above ratio  
 is greater than 50/50, the strength of the porous  
 membrane decreases, thereby causing membrane break.

Subsequently, (c) a hydrophobic organic  
 15 solvent is evaporated from the hydrophobic organic  
 solvent solution casted on the supporting porous  
 membrane in an environment wherein the relative  
 humidity around the liquid face is between 20% and

100%, and during this process, a porous membrane having a honeycomb pore structure is formed.

[0035]

As a method of evaporating such a hydrophobic organic solvent, any method may be applied, as long as the relative humidity around the liquid face (a position approximately 2 cm apart from the liquid face in the vertical direction during formation of a membrane) is adjusted between 20% and 100%. Examples of such a method may include a method of increasing the temperature in the peripheral environment of membrane formation, a method of appropriately decreasing the atmospheric pressure in the membrane formation environment, and a method of gently blowing suitable gas to the liquid face. Of these, the method of blowing gas to the liquid face is preferable because formation of a micro water droplet used as a template of the porous membrane is easy, and also because humidity is easily controlled and a simple device is thereby used.

When gas is blown to the liquid face to evaporate the organic solvent, any type of gas may be used, as long as it is blown to the hydrophobic organic solvent solution, so as to effectively evaporate the hydrophobic organic solvent. Gas that is chemically inactive to the porous membrane, the supporting porous membrane, and the hydrophobic organic solvent solution during the membrane formation process, is preferable.

Specific examples of such gas may include air, nitrogen, oxygen, helium, argon or the like, and mixed gas thereof. Taking into consideration cost performance, air is preferable.

5           As a method of blowing gas to the hydrophobic organic solvent solution, a method of establishing a pump on the gas-supplying side, supplying gas through a suitable nozzle, and blowing it, is used. In the case of using a hermetically sealed thermo-hygrostat box or  
10       the like, a method of reducing the pressure in the box, aspirating gas from the outside, and then blowing the gas to the hydrophobic organic solvent solution through a suitable nozzle, is used.

[0036]

15       When a hydrophobic organic solvent is evaporated by gas blowing or the like, such gas blowing is carried out in an environment wherein the relative humidity around the membrane is between 20% and 100%. Such relative humidity is preferably between 30% and  
20       90%, and more preferably between 35% and 80%. When the relative humidity is less than 20%, the growth of a water droplet acting as a template for forming a pore is insufficient. Thus, a uniform honeycomb pore structure is hardly formed, and the through-pore percentage is also deteriorated.  
25

Such "an environment wherein the relative humidity around the membrane is between 20% and 100%" may be set by adjusting the relative humidity of the

membrane formation environment as a whole, such as in a thermo-hygrostat box. When a gas blowing method is applied, such an environment can be set by adjusting the relative humidity of the gas to be blown.

5           A hydrophobic organic solvent is evaporated, and during such a process, a micro water droplet forming on the surface of a solution acts as a template, so as to form a porous membrane having a uniform pore structure is formed on the supporting  
10 porous membrane. After formation of pores, the liquid retained by the supporting porous membrane is directly removed by drying, or it is once immersed in alcohol or the like for liquid substitution, and it is then removed by drying.

15 [0037]

Various types of surface modification can be performed on the supporting porous membrane used in the production process of the present invention or the obtained composite porous membrane, depending on  
20 various requirements in production process or in use, such as the improvement of water permeability, the improvement of separability by introduction of a selective functional group, or suppression of the adhesiveness of biological substances or the like.

25           In particular, in the case of the production process of a composite porous membrane preferably used in the present invention, namely, a production process comprising allowing the supporting porous membrane to

retain water to form a porous membrane, if the hydrophobicity of the supporting porous membrane is strong, it becomes impossible to allow the supporting porous membrane to uniformly retain water thereon.

- 5 Thus, a hydrophobic organic solvent solution used for forming a porous membrane penetrates into the supporting porous membrane, and thereby, it becomes difficult for the supporting porous membrane to smoothly retain the above hydrophobic organic solvent
- 10 10 solution thereon. Accordingly, there are some cases where it becomes difficult to produce a composite porous membrane with a desired form. In such a case, it is preferable that a hydrophilic treatment be performed on the surface of the supporting porous
- 15 15 membrane, so as to enhance water retentivity.

For the aforementioned reasons in terms of production, when a hydrophilic treatment has previously been performed on the supporting porous membrane, or when such a hydrophilic treatment is performed for the

20 20 improvement of the performance of the obtained composite porous membrane in practical use (the improvement of water permeability, blood compatibility, protein non-adsorptive properties, etc.), it is preferable to introduce a suitable hydrophilic

25 25 functional group on the surface of the membrane, as necessary.

Moreover, for example, when a composite porous membrane is used as a blood filtration membrane

or a filter element of a leukocyte removal filter, it  
is effective for the improvement of the performance to  
introduce in a well-balanced manner, both a hydrophilic  
functional group for suppressing non-selective  
5 adsorption of blood cell components and a nitrogen-  
containing basic functional group for expressing  
selective affinity for leukocytes.

[0038]

The term "hydrophilic functional group" is  
10 used herein to mean a functional group having affinity  
for water molecules. Such a hydrophilic functional  
group includes various types of known hydrophilic  
functional groups. Specific examples may include  
functional groups having relatively high  
15 hydrophilicity, such as an alcoholic hydroxyl group, a  
phenol hydroxyl group, a carboxyl group, a sulfone  
group, a carbonyl group, an ester group, an ether  
group, an amide group, an N-monosubstituted amide  
group, and an N,N-disubstituted amide group. It is  
20 preferable to introduce these hydrophilic functional  
groups, singly or in combination of two or more types.  
It is particularly preferable to introduce nonionic  
hydrophilic functional groups such as an alcoholic  
hydroxyl group, a carbonyl group, an ester group, an  
ether group, an amide group, or an N-N-disubstituted  
25 amide group, singly or in combination of two or more  
types.

Examples of a "nitrogen-containing basic

functional group" introduced for the purpose of expressing selective affinity for leukocytes may include nitrogen-containing aromatic groups such as an aliphatic primary amino group, an aliphatic secondary 5 amino group, an aliphatic tertiary amino group, a pyridyl group, a bipyridyl group, or an imidazole group. It is preferable to introduce these nitrogen-containing basic functional groups, singly or in combination of two or more types. Since such an 10 aliphatic primary amino group ( $-NH_2$ ), an aliphatic secondary amino group, and an aliphatic tertiary amino group have lower hydrophobicity than that of an aromatic amino group, it is particularly preferable to use such aliphatic amino groups to realize selective 15 affinity for leukocytes. Specifically, such an aliphatic secondary amino group has the structure  $-NHR^1$ , wherein  $R^1$  is not particularly limited but may have any structure. Examples may include linear alkyl groups such as a methyl group, an ethyl group, or a propyl 20 group, and branched alkyl groups such as an isopropyl group. The number of carbon atoms or structure of such an alkyl group is not particularly limited. In addition, one or more hydrogen atoms thereof may also be substituted with any given functional groups having 25 a hydroxyl group, an ester group, a carbonyl group, or an ether group. Moreover, such an aliphatic tertiary group has the structure  $-NR^2R^3$ , wherein  $R^2$  and  $R^3$  may have various structures as with  $R^1$ , and further where  $R^2$

and R<sup>3</sup> may be either identical to or different from each other.

Among them, an aliphatic tertiary amino group has a preferred structure, and thus a functional group having such an aliphatic tertiary amino group is effective as a leukocyte selective affinity functional group. Specific examples of such a functional group may include a dimethylamino group, a diethylamino group, an ethylmethylamino group, a diethanolamino group, a 2-(dimethylamino)ethyl group, a 3-(dimethylamino)propyl group, a 2-(diethylamino)ethyl group, and a 3-(diethylamino)propyl group.

[0039]

Examples of a specific method of introducing a functional group such as a hydrophilic functional group or a nitrogen-containing basic functional group into the membrane surface may include: (a) a method of introducing a functional group of interest or the like into a functional group that is originally present on the surface of a membrane substrate by a polymer reaction; (b) a method of applying electron beam or  $\gamma$ -ray to the surface of a membrane substrate to generate radicals and then allowing a monomer having a functional group of interest to act on such radicals for graft polymerization; (c) various types of living polymerization methods, which comprise introducing a necessary initiator group into the surface of a membrane substrate and then adding a catalyst or the

like as necessary (for example, the living radical polymerization method or the living anion polymerization method); and (d) a method of coating the surface of a membrane substrate by the immersion method 5 or the spray method. In particular, the coating method described in (d) above is preferable because the type, amount, polymerization chain distribution of a functional group to be introduced can easily be designed during the synthetic reaction of a coating 10 polymer, and also because such a coating process itself is simple, providing high productivity.

When a hydrophilic functional group is introduced into the supporting porous membrane or composite porous membrane by the coating method, the 15 type of a hydrophilic functional group-containing monomer used for the synthesis of the coating polymer is not particularly limited. A monomer containing a nonionic hydrophilic functional group is particularly preferable. Examples of such a compound may include: 20 (meth)acrylic esters having an alcoholic hydroxyl group, such as 2-hydroxyethyl methacrylate or 2-hydroxypropyl methacrylate; (meth)acrylamides including (meth)acrylamide, N-monosubstituted (meth)acrylamide, and N,N-disubstituted (meth)acrylamide such as N,N- 25 dimethylacrylamide or N,N-diethylacrylamide; and (meth)acrylic esters of alkoxy polyethylene glycol having a polyoxyethylene group having 1 to 100 repeating units of -CH<sub>2</sub>CH<sub>2</sub>O-.

[0040]

When the hydrophilicity of a coating polymer is too high, elution of a coating polymer into a filtrate or a cell culture solution in practical use causes a problem in many cases. (Such low elution properties are important particularly for the medical use.) It is preferable that for the purpose of suppression of such elution properties, other types of hydrophobic monomers are copolymerized at a suitable amount, so as to synthesize a coating polymer.

In addition, when a nitrogen-containing basic functional group is introduced into the supporting porous membrane or composite porous membrane by the coating method, the type of a monomer containing a nitrogen-containing basic functional group used for the synthesis of the coating polymer is not particularly limited. A monomer containing an aliphatic tertiary amino group is particularly preferable. Examples of such a compound may include 2-(N,N-dimethylamino)ethyl (meth)acrylate, 2-(diethylamino)ethyl (meth)acrylate, 2-(ethylmethylamino)ethyl (meth)acrylate, 2-(diethanolamino)ethylethyl (meth)acrylate, 2-(dimethylamino)propylethyl (meth)acrylate, 3-(dimethylamino)propyl (meth)acrylate, 3-(diethylamino)propyl (meth)acrylate, 2-(diethanolamino)propyl (meth)acrylate, and 3-(diethanolamino)propyl (meth)acrylate.

When the coating method is used as a method

of modifying the surface of a supporting porous membrane used in the production process of the present invention or the surface of the obtained composite porous membrane, a coating polymer has previously been 5 synthesized, and the coating polymer is then dissolved in a suitable solvent to prepare a coating solution.

[0041]

Examples of a method of coating such a supporting porous membrane or composite porous membrane 10 with a coating solution may include: a method of immersing a supporting porous membrane or composite porous membrane to be coated (a target membrane to be coated) in a coating solution; a method of setting a target membrane to be coated to a filter holder and 15 then allowing a coating solution to pass through it; and a method of spraying such a coating solution to a target membrane to be coated. Of these, in order to easily conduct coating with high uniformity, the immersion method is preferable.

20 The type or composition of a coating polymer is not limited, as long as it is dissolved in a suitable solvent and then a necessary amount of hydrophilic functional group or nitrogen-containing basic functional group can be introduced by coating 25 into at least the surface portion of a supporting porous membrane or composite porous membrane. Examples of such a coating polymer may include: a blend of a polymer obtained by polymerization of one or more types

of the aforementioned hydrophilic functional group-containing monomers with a polymer obtained by polymerization of one or more types of nitrogen-containing basic functional group-containing monomers; 5 and a copolymer obtained by copolymerization of one or more types of hydrophilic functional group-containing monomers with one or more types of nitrogen-containing basic functional group-containing monomers. When the coating polymer is a copolymer, it may be either a 10 random copolymer or a block copolymer.

With regard to the molecular weight of such a coating polymer, the weight average molecular weight ( $M_w$ ) is preferably between  $1.0 \times 10^3$  and  $2.0 \times 10^6$ , more preferably between  $5.0 \times 10^3$  and  $1.5 \times 10^6$ , and most 15 preferably between  $1.0 \times 10^4$  and  $1.0 \times 10^6$ . When  $M_w$  is less than  $1.0 \times 10^3$ , the entangling effect of molecular chains decreases, and immobilization on the surface portion of a porous membrane thereby becomes insufficient. Thus, there are some cases where a 20 coating polymer is eluted when used. In contrast, when  $M_w$  exceeds  $2.0 \times 10^6$ , its solubility in a solvent decreases, and the uniformity of a solution may thereby decrease. In addition, the viscosity of a solution becomes too high, and there are some cases where it 25 becomes impossible for the surface of a membrane material to be uniformly coated with the solution. Herein,  $M_w$  is a value obtained by the gel permeation chromatography method (GPC; relative to standard

polystyrene).

[0042]

The type of a solvent, in which a coating polymer is dissolved, is not limited, as long as the 5 solvent does not cause significant swelling or dissolution of a supporting porous membrane or composite porous membrane, and in particular, a porous membrane constituting a composite porous membrane, and as long as the coating polymer is sufficiently 10 dissolved therein, and ultimately the solvent is removed from the composite porous membrane or the supporting porous membrane. Thus, various types of solvents can be used depending on the type of a coating polymer. Examples of such a solvent may include: 15 alcohols such as methanol, ethanol, propanol, or butanol; ketones such as acetone or methyl ethyl ketone; esters such as ethyl acetate; aromatic hydrocarbons such as benzene, toluene, or xylene; aliphatic hydrocarbons such as hexane, cyclohexane, 20 methylcyclohexane, or decalin; halogenated hydrocarbons such as chloroform, dichloromethane, or dichloroethane; sulfur-containing solvents such as dimethyl sulfoxide; and amides such as N,N-dimethylformamide or N,N-dimethylacetamide. These solvents can be used singly 25 or in combination of two or more types. Of these, alcohols are preferable in terms of moderate drying rate, handlability, and high affinity for a polymer having a hydrophilic functional group. In particular,

ethanol is practically extremely preferable because it has low toxicity to human bodies. If necessary, an appropriate amount of water is mixed for the purpose of finely adjusting the hydrophilicity or hydrophobicity 5 of a solvent.

[0043]

When the coating method is used as a method of modifying the surface of a supporting porous membrane used in the production process of the present 10 invention or the surface of the obtained composite porous membrane, a coating polymer has previously been synthesized, and the synthesized coating polymer is dissolved in a suitable solvent, so as to prepare a coating solution.

15 When a hydrophilic functional group or nitrogen-containing basic functional group has previously been introduced by coating into a supporting porous membrane, the concentration of a polymer in a coating solution is preferably between 0.01 wt % and 50 20 wt %, more preferably between 0.1 wt % and 30 wt %, and most preferably between 0.5 wt % and 20 wt %. If the concentration of a coating solution is less than 0.01 wt %, coating becomes insufficient, and the surface of the supporting porous membrane is thereby partially 25 exposed. In contrast, if such a concentration exceeds 50 wt %, since the viscosity of a solution increases, it becomes difficult for the supporting porous membrane to be uniformly coated with the solution, or the pores

of the supporting porous membrane are likely to be occluded.

When a hydrophilic functional group or nitrogen-containing basic functional group is introduced into the obtained composite porous membrane by coating, the concentration of a polymer in a coating solution is preferably between 0.01 wt % and 10 wt %, more preferably between 0.05 wt % and 5 wt %, and most preferably between 0.1 wt % and 1 wt %. If the concentration of a coating solution is less than 0.01 wt %, coating becomes insufficient, and the surface of the porous membrane is thereby partially exposed. In contrast, if such a concentration exceeds 10 wt %, since the viscosity of a solution increases, it becomes difficult for the porous membrane to be uniformly coated with the solution, or the pores of the porous membrane are likely to be occluded.

A preferred coating process comprises: immersing a supporting porous membrane or composite porous membrane for a certain period of time in a coating polymer solution that has previously been adjusted to a suitable concentration; removing it from the solution; and squeezing the membrane with a nip roll, or blowing air or nitrogen gas thereto, so as to remove an unnecessary coating polymer solution. Either a continuous process or a batch process can be adopted.

[0044]

The time required for a supporting porous

membrane or composite porous membrane to be immersed in a coating polymer solution is preferably between 0.5 and 60 seconds, more preferably between 1 and 30 seconds, and most preferably between 2 and 10 seconds.

- 5 If such an immersion time is less than 0.5 seconds, there are cases where coating becomes ununiform and insufficient. Even if such an immersion time exceeds 60 seconds, the amount coated rarely increases. In addition, depending on the type of a porous membrane,
- 10 there are cases where the porous membrane itself swells.

According to the production process of the present invention, since a porous membrane penetrates into fine unevenness on the surface of a supporting porous membrane (which is an entangled fiber portion in a case where the supporting porous membrane is a fiber medium such as a non-woven fabric or mesh) during the process of forming the porous membrane on the surface of the supporting porous membrane, it becomes possible to realize a state where the supporting porous membrane strongly adheres to a porous membrane. On the other hand, in a case where a porous membrane is once formed on a solid substrate such as a glass as with the conventional process, and where it is then peeled and overlaid on a supporting porous membrane, since the porous membrane does not adhere to the supporting porous membrane, a displacement is generated between both membranes by pulling them, for example, and as a

result, the porous membrane is easily broken.

The composite porous membrane obtained by the production process of the present invention, which includes a porous membrane, has extremely high strength. Thus, it is extremely easy to handle the membrane, when it is used. In addition, the above composite porous membrane can be processed into various forms such as a roll-, cylindrical, or pleated-form, and then used.

Next, the leukocyte removal filter device of the present invention will be described.

The leukocyte removal filter device of the present invention is a filter device having a first filter located on the entrance side of a hemocyte suspension to be treated and a second filter located on the exit side thereof. The term "hemocyte suspension to be treated" is used to mean a hemocyte suspension before being filtrated with a filter.

[0045]

The capability of the first filter to remove leukocytes is between 1.0 and 3.5, preferably between 1.3 and 3.3, and more preferably between 1.5 and 3.0, for 450 cm<sup>3</sup> of the hemocyte suspension to be treated.

In the case of the first filter, the "capability of removing leukocytes" is obtained using the following formula (1) based on the concentrations of leukocytes in a hemocyte suspension before and after filtration obtained when 450 cm<sup>3</sup> of the hemocyte

suspension to be treated is passed through the first filter.

Capability of removing leukocytes =  $-\log \left( \frac{\text{leukocyte concentration in the hemocyte suspension after filtration}}{\text{leukocyte concentration in the hemocyte suspension before filtration}} \right) \dots (1)$

If the capability of the first filter of removing leukocytes is less than 1.0, the second filter consisting of a composite porous membrane may be 10 occluded with large quantities of leukocytes.

Moreover, if such occlusion of the second filter is intended to be prevented, the second filter with an extremely large area is required. Thus, the size of a leukocyte removal filter becomes significantly larger 15 than the conventional level, and it becomes difficult to handle such a filter of large size in medical sites. In contrast, if the capability of the first filter of removing leukocytes exceeds 3.5, the volume of a filter element in the first filter becomes large, and thus, 20 the "effect of reducing the loss of a hemocyte suspension by reduction in such a volume of filter element," which is the effect of the present invention, decreases.

When the amount of the hemocyte suspension to 25 be treated used is too small, the ratio of the amount of a hemocyte suspension remaining in a filter after filtration to a certain amount of the hemocyte suspension to be treated (namely, the loss of a

hemocyte suspension) increases, and thus it results in poor filtration efficiency. Accordingly, the amount of the hemocyte suspension to be treated used is preferably 15 cm<sup>3</sup> or more. If the amount of the 5 hemocyte suspension to be treated used is too large, there are cases where the second filter consisting of a composite porous membrane is occluded with large quantities of leukocytes. If the amount is further larger, the presence of not only leukocytes but also 10 large quantities of blood cell components causes significant reduction in the filtration rate of the first filter or occlusion thereof. Thus, the amount of the hemocyte suspension to be treated used is preferably 2,000 cm<sup>3</sup> or less. The amount of the 15 hemocyte suspension to be treated is more preferably between 50 and 1,500 cm<sup>3</sup>, further more preferably between 100 and 1,000 cm<sup>3</sup>, and most preferably between 200 and 600 cm<sup>3</sup>.

[0046]

20           The first filter may have any structure, as long as the capability of removing leukocytes is between 1.0 and 3.5. As with the aforementioned specific examples of the supporting porous membrane of a composite porous membrane, specific examples of such 25 a first filter may include: non-woven fabrics obtained from natural fibers, synthetic polymer fibers, regenerative polymer fibers, inorganic fibers including a glass fiber as a typical example, organic/inorganic

composite fibers, or the like; and porous bodies (porous membranes) having three-dimensional network continuous pores, which are obtained from organic polymer materials that are fused by heating, dissolved 5 in a solvent in the form of a solution, or plasticized using a plasticizer, according to the foaming method, the phase separation method (thermotropic phase separation method or wet phase separation method), the drawing method, the sintering method, or the like.

10 Further examples may include: woven fabrics or kitted fabrics obtained from natural fibers, synthetic polymer fibers, regenerative polymer fibers, glass fibers, organic/inorganic composite fibers, etc.; and various types of meshes consisting of an organic material, an 15 inorganic material, a metal material, or a hybrid material thereof.

[0047]

Of these, a non-woven fabric obtained from an organic polymer fiber, or a porous body obtained by the 20 phase separation method, which forms relatively uniform three-dimensional continuous pores, is preferable.

Examples of the material of an organic polymer forming a non-woven fabric itself may include polyethylene terephthalate, polypropylene, a cellulose 25 derivative, polyamide, and polyacrylonitrile. Of these, polyethylene terephthalate is particularly preferable.

In addition, as a fiber constituting such a

non-woven fabric, an extra fine fiber is preferable.

In terms of strength and ability to capture leukocytes, the fiber diameter is preferably between 0.3 and 3  $\mu\text{m}$ , more preferably between 0.5 and 2  $\mu\text{m}$ , and most

5 preferably between 0.5 and 1.5  $\mu\text{m}$ .

In terms of clogging with leukocytes or increase in the loss of pressure, the average pore size of a non-woven fabric is preferably 2  $\mu\text{m}$  or more. In addition, in terms of ability to capture leukocytes, it 10 is preferably 30  $\mu\text{m}$  or less. The average pore size is more preferably between 2 and 20  $\mu\text{m}$ , and most preferably between 2 and 10  $\mu\text{m}$ .

When a non-woven fabric is used as a filter element, in order to improve capability of removing 15 leukocytes or prevent clogging, two or more types of non-woven fabrics that are different in terms of average fiber diameter, average pore size, weight, or the like, may be used in combination, or at least one type of porous body other than a non-woven fabric 20 having continuous pores in a three-dimensional network state may also be used with the combination of at least one type of non-woven fabric.

When a filter element is filled in a filter holder that is used for a leukocyte removal filter 25 device, the filling density is preferably 0.1 g/cm<sup>3</sup> or more, in terms of capability of removing leukocytes. In addition, in terms of clogging with blood cells or increase in the loss of pressure, the filling density

is preferably  $0.5 \text{ g/cm}^3$  or less. It is more preferably between  $0.1$  and  $0.3 \text{ g/cm}^3$ , and most preferably between  $0.15$  and  $0.25 \text{ g/cm}^3$ .

With regard to the form of the above filter element, or the form of the first filter constituted with a single (a single slice) filter element or the combined use of several (several slices of) filter elements, any type of form such as a flat membrane (plate) form, a cylindrical form (hollow form), or a bag form can be adopted, as long as it is able to filtrate blood. In terms of handlability, the form of a flat membrane is preferable. In such a case, it is preferable that one or several filter elements be laminated so as to constitute the first filter. When several filter elements are laminated, the filter elements may have the same material, micro structure, average pore size, pore size distribution, and membrane thickness. Moreover, several or all these factors may be different. Furthermore, a single filter element (a single slice) may be uniform in terms of micro structure, average pore size, pore size distribution, etc., or such a single filter element may have an ununiform structure such as a gradient structure.

[0048]

The size of the first filter is not limited, as long as its capability of removing leukocytes is between  $1.0$  and  $3.5$  for  $450 \text{ cm}^3$  of the hemocyte suspension to be treated. However, if the size is too

large, workability decreases in medical sites. In addition, as the holder size of a filter increases, the cost significantly increases on the side of manufacturers. Thus, the effective area of the first 5 filter as a practical value is preferably between 4 and 300 cm<sup>2</sup>, more preferably between 10 and 250 cm<sup>2</sup>, and most preferably between 10 and 200 cm<sup>2</sup>.

The effective area of the first filter means a flat area of a filter portion through which the 10 hemocyte suspension actually passes, from which a filter nipping portion (a portion for fixing the filter to the filter holder) is excluded. Thus, it does not mean an area including the surface of internal pores in the membrane.

15 For the purpose of sufficiently conducting introduction of a new functional group by the coating method, etc., or immobilization of such a functional group (for the purpose of suppressing elution of a coating material to the minimum during the use), the 20 surface of the filter element may be treated with suitable agents such as acid or alkali, or with plasma or electron beam.

When a non-woven fabric obtained from an organic polymer fiber, a porous material having 25 continuous pores in a three-dimensional network state obtained by the phase separation method, or the like, is used as a first filter, if capability of removing leukocytes between 1.0 and 3.5 for 450 cm<sup>3</sup> of the

hemocyte suspension to be treated cannot be achieved by the direct use of such a material, the surface portion of the filter element capable of coming into contact with the hemocyte suspension is preferably modified by 5 chemical modification or the like. A known method of introducing a hydrophilic functional group and a nitrogen-containing basic functional group in a well-balanced manner is particularly effective.

[0049]

10           The expression "the surface portion of the filter element capable of coming into contact with the hemocyte suspension" does not only mean the front and back sides of a flat membrane, for example, but also includes the surface of internal fine pores existing in 15 the flat membrane. When such a filter element is a non-woven fabric for example, the entire surface of fibers constituting the non-woven fabric (excluding an entangled fiber portion) means the surface portion of a filter element.

20           A method of introducing a hydrophilic functional group or nitrogen-containing basic functional group into at least the surface portion of a filter element is not particularly limited. Such a method is not particularly limited, as long as it is a 25 method that does not significantly occlude the fine pores of the filter element, or when the surface of the original filter element exhibits non-selective adsorption of blood cell components, a method of

uniformly introducing a necessary functional group without exposing the above surface. Examples of such a method may include those described as methods of modifying the surface of the composite porous membrane 5 of the present invention or the surface of a supporting porous membrane constituting it. The coating method is particularly preferable.

In addition, the surface portion of a filter capable of coming into contact with a hemocyte 10 suspension preferably consists of a material that does not affect blood cells. The term "material that does not affect blood cells" is used to mean a material that does not significantly impair the original performance of blood cell components recovered after filtration 15 (mainly, erythrocytes, thrombocytes, or small quantities of leukocytes) by the contact of blood cells with the material during the filtration, or a material that does not excessively activate blood cell components. As such a material, a polymer material 20 having a hydrophilic functional group is adequate. As such a hydrophilic functional group, one or more types can be selected from the aforementioned group of hydrophilic functional groups.

It is preferable, if a material constituting 25 a filter element used as a first filter originally has such a hydrophilic functional group. However, when such a filter element contains no such hydrophilic functional groups, or when it contains a very small

amount of hydrophilic functional group and thus it may affect blood cells, it is preferable that a hydrophilic functional group be introduced into at least a surface portion capable of coming into contact with a hemocyte 5 suspension, as necessary, by a suitable method selected from among several surface modification methods as described above. In this case also, the coating method is preferably applied, and a hydrophilic functional group can be introduced by such a method.

10 [0050]

Next, the second filter of the leukocyte removal filter device of the present invention will be described.

The second filter is composed of one or more 15 composite porous membranes of the present invention as described above.

The second filter has any form such as a flat membrane form or a cylindrical form, as long as it is able to filtrate blood. The second filter with a flat 20 membrane form is easily handled, and thus it is preferable. When several slices of composite porous membranes are used, the material, opening ratio, average pore diameter, standard deviation of pore diameter, thickness, the structure of an internal 25 membrane, or the like, of a porous membrane constituting each composite porous membrane, may be completely identical. Otherwise, several factors or all factors may differ from one another. In the case

of a supporting porous membrane constituting a composite porous membrane also, the material, average pore size, or the like, may be identical, or several or all factors may differ from one another.

5           It is preferable that the surface portion of the second filter capable of coming into contact with a hemocyte suspension consist of a material that does not affect blood cell components, as in the case of the first filter, or a material that has low affinity for  
10 blood cell components and hardly causes non-selective adhesion of blood cell components. (There is a possibility that the composite porous membrane is occluded due to adhesion of blood cells.) As described in the section for the first filter, it has been known  
15 that a polymer material with high hydrophilicity is suitable as such a material. Thus, it is preferable that at least the surface portion of a composite porous membrane have one or more types selected from among the aforementioned hydrophilic functional groups.

20           It is preferable that a material forming a composite porous membrane originally have a hydrophilic functional group. However, when a composite porous membrane contains no such hydrophilic functional groups at least on the surface portion thereof, or when it  
25 contains a very small amount of hydrophilic functional group and thus it may affect blood cells, it is preferable that the surface be modified by coating or the like, and that it be then used as a second filter,

as described above.

[0051]

A coating polymer that is to be introduced into at least the surface portion of a composite porous membrane by the coating method is preferably obtained by polymerization (copolymerization) of one or more types selected from among monomer species having a hydrophilic functional group. A nitrogen-containing basic functional group may also be contained in a coating polymer introduced into a composite porous membrane within a range where it does not cause non-selective adsorption of blood cell components, or within a range where it does not affect blood cell components. For such introduction, one or more types of the aforementioned monomer species having a nitrogen-containing basic functional group are preferably used. In terms of the improvement of productivity on the side of manufacturers of filter devices and cost reduction, it is advantageous and preferable that the coating polymer used for the first filter be also used for the second filter.

From the viewpoint of the number of pores in the second filter, clogging with leukocytes, and the amount of a hemocyte suspension to be treated, the effective area of the second filter is 4 cm<sup>2</sup> or more. Also, from the viewpoint of the size of a filter device and operability in medical sites, the effective area of the second filter is 300 cm<sup>2</sup> or less. The effective

area is preferably between 10 and 200 cm<sup>2</sup>, more preferably between 10 and 150 cm<sup>2</sup>, and most preferably between 10 and 100 cm<sup>2</sup>.

The effective area of the second filter means  
5 a flat area of a filter portion through which the hemocyte suspension actually passes, from which a filter nipping portion (a portion for fixing the filter to the filter holder) is excluded. Thus, it does not mean an area including the surface of internal pores in  
10 the membrane.

The leukocyte removal filter device of the present invention is a filter device having a first filter located on the entrance side of a hemocyte suspension and a second filter located on the exit side  
15 thereof. Basically, the leukocyte removal filter device may have any structure, as long as it is constructed such that a whole hemocyte suspension passed through the first filter is successively filtrated through the second filter. When the second  
20 filter is established on the hemocyte suspension entrance side, there are cases where a composite porous membrane may be occluded with large quantities of leukocytes.

[0052]

25 It is also possible that each of the first and second filters be filled in a different filter holder, and both holders be connected using a tube or the like and be used (division type). In this case,

this structure is characterized in that the form and size of both filters of the present invention can be determined independently. For example, if the effective area of the second filter is determined to be 5 2 times larger than that of the first filter, the clogging of the second filter hardly occurs, and thus it becomes possible to reduce the volume of a filter element of the first filter.

It is also possible to fill the first and 10 second filters in a single filter holder and use it (integral type). In the case of such an integral type, since only one filter holder is used, it is preferable in terms of production cost. In addition, the form of a filter holder is devised in various ways, so that the 15 same effects as those of the aforementioned division type can be obtained.

Practically, an integral-type structure wherein the flat membrane-type first filter (which is, for example, obtained by laminating several non-woven 20 fabrics) is overlaid on the second filter formed by laminating one or more slices of composite porous membranes of the same size and wherein the obtained filter is filled in a simple form of filter holder is preferably used in terms of operability in medical 25 sites and production cost.

[0053]

Fig. 5 is a conceptional view showing the basic structure of an integral-type leukocyte removal

filter device. This leukocyte removal filter device basically consists of a first filter (2), a second filter (3), a filter holder (4), a hemocyte suspension entrance (5), and a filtrated hemocyte suspension exit 5 (6). In this conceptional view, the first filter is conveniently disposed apart from the second filter to clearly explain them in the drawing. However, in an actual situation, both filters are laminated (attached) to each other, and they are filled in a filter holder. 10 Moreover, in the filter holder shown in Fig. 5, as a matter of convenience for expression with the drawing, there are many spaces, which do not exist in the actual filter element. However, such spaces result in the loss of a hemocyte suspension, and thus they do not 15 exist actually.

In addition, when a composite porous membrane used as a second filter consists of a single porous membrane and a single supporting porous membrane, it is preferable that the second filter (composite porous membrane) be disposed in the filter holder, so that the porous membrane face can be located on the hemocyte suspension entrance side. If the second filter is disposed such that the supporting porous membrane face is located on the hemocyte suspension entrance side, 20 filtration resistance increases, and thus filtration efficiency may significantly decrease. 25

The capability of the leukocyte removal filter device of the present invention to remove

leukocytes is preferably 4.0 or more, more preferably 4.5 or more, and most preferably 5.0 or more, for 450 cm<sup>3</sup> of the hemocyte suspension to be treated. If such capability of removing leukocytes is less than 4.0,

5 side effects caused by residual leukocytes occur at high probability during blood transfusion. In order to achieve a significant effect of reducing the volume of a filter element of the leukocyte removal filter device, the capability of removing leukocytes is

10 preferably 8.0 or less.

The volume of filter element V (the volume of filter element consisting of the first filter volume and the second filter volume) of the leukocyte removal filter device is between 2 and 18 cm<sup>3</sup>, preferably

15 between 2 and 15 cm<sup>3</sup>, more preferably between 3 and 12 cm<sup>3</sup>, and most preferably between 3 and 10 cm<sup>3</sup>. If such a volume of filter element is less than 2 cm<sup>3</sup>, the capability of the first filter of removing leukocytes becomes insufficient. In contrast, if such a volume of

20 filter element exceeds 18 cm<sup>3</sup>, the effect of reducing a filter element decreases, and as a result, the effect of reducing the loss of a hemocyte suspension also decreases.

The volume of filter element V (cm<sup>3</sup>) means the

25 void volume of a filter element. The value V can be obtained by filling a filter holder containing a filter element with a hemocyte suspension or an alternative liquid such as a normal saline solution and then

actually measuring the volume ( $\text{cm}^3$ ) of the liquid filled in the filter holder.

With regard to the leukocyte removal filter device of the present invention, when the supporting 5 porous membrane of a composite porous membrane used as a second filter is made from the same material as that of a first filter, and also when the amount of a porous membrane used of a composite porous membrane is substantially negligible when compared with that of the 10 first filter, the value calculated using the following formula (2) can be used as such V.

$$V = W_f[(1/d) - (1/\rho)] \dots (2)$$

Herein, d ( $\text{g}/\text{cm}^3$ ) represents the filling density of the total filter element consisting of the 15 first filter and the second filter that are filled in the filter holder;  $W_f$  ( $\text{g}$ ) represents the weights of the first and second filters filled therein; and  $\rho$  ( $\text{g}/\text{cm}^3$ ) represents the density of a material forming the first filter and the supporting porous membrane of the second 20 filter (composite porous membrane). For example, when the first filter and the supporting porous membrane are non-woven fabrics made from polyethylene terephthalate,  $\rho$  is approximately 1.3.

[0054]

25 The cell culture diaphragm of the present invention will be described.

The cell culture diaphragm of the present invention is used to divide different cell groups in a

cell culture solution in a state where they are allowed to come into contact with each other, so as to co-culture the cells. It is a cell culture diaphragm using the composite porous membrane of the present  
5 invention.

In the present invention, the term "co-culture of cells" is used to include not only the simultaneous growth of two or more types of cell groups in a cell culture solution, but also include a case  
10 where the growth and/or differentiation of at least one type of cells is promoted by contact with cell groups that are different from each other, and a case where at least one type of cells is allowed to grow in number, while suppressing the differentiation thereof.

15 When cells are cultured using the cell culture diaphragm of the present invention, the cell culture diaphragm is disposed in a cell culture solution. Depending on the number and form of the diaphragm, at least two culture regions separated by  
20 the diaphragm of the present invention are obtained. In such at least two culture regions adjacent to each other, different types of cells are co-cultured. For example, two cell culture diaphragms, each of which is cut into a square of the same size, are laminated such  
25 that the supporting porous membranes thereof (for example, non-woven fabrics) are located inward, and 3 sides thereof are then sealed by heat sealing, so as to obtain a bag-form diaphragm sheet. Such a diaphragm

sheet is disposed in a cell culture solution (the opening portion of the bag is exposed from the liquid face, or it is closed). Thus, two culture regions adjacent to each other that are separated by a porous membrane can be obtained inside and outside the bag-form diaphragm sheet (inside and outside the bag). As a result, cells can be co-cultured in the two culture regions that are located inside and outside. Likewise, if two bag-form diaphragm sheets are disposed in a cell culture solution, three culture regions separated by a porous membrane can be obtained. Further, if three bag-form diaphragm sheets are disposed therein, four culture regions can be obtained. Moreover, for example, when such a cell culture diaphragm is adhered to one end face of a glass tube to prepare an integrated cup-type container, and when such an integrated cup-type container is placed in a well of a culture plate, two culture regions can be obtained inside and outside the cup in the well.

That is to say, different cell groups are co-cultured in at least two culture regions adjacent to each other that are separated by a porous membrane, and further, the average pore size of a supporting porous membrane and that of a porous membrane are adjusted depending on the size of the cell to be cultured, so as to conduct the co-culture of cells enabling effective intracellular contact.

Since the cell culture diaphragm of the present invention can be processed into a desired form, the separation and recovery of grown cells of interest can be extremely easily carried out. For example, in 5 the case of co-culture using the aforementioned bag-form diaphragm sheet, when cells of interest have been allowed to grow outside the bag-form sheet, the cells of interest can be easily separated and recovered only by removing the bag-form diaphragm sheet from the 10 culture solution. Moreover, in the case of co-culture using the aforementioned cup-type culture apparatus for example, even if cells of interest have been allowed to grow inside the cup, they can be easily separated and recovered. (Naturally, pipetting or a centrifugal 15 operation is required, as necessary.)

According to the cell culture process of the present invention, at least two types of cell groups are divided in a cell culture solution in a state where they are allowed to come into contact with each other, 20 and then co-cultured. The combination of cell groups to be co-cultured is not limited. The combination of cell groups, the contact with which affects the growth or differentiation of at least one type of cells, is preferable. The combination of cell groups, which are 25 come into contact with each other, thereby promoting the growth and/or differentiation of at least one type of cells, or thereby promoting only the growth in number while suppressing differentiation, is

particularly preferable.

Examples of such a combination of cell groups may include: the combination of "a hematopoietic stem cell group with a mouse bone marrow-derived stromal cell group;" and the combination of "a hematopoietic stem cell group with a human vascular endothelial cell group," which preferentially promotes only the growth in number of the hematopoietic stem cells due to intracellular contact in a state where the cells are undifferentiated. As a cell group of interest that is allowed to grow by intracellular contact, a hematopoietic stem cell group is preferable because the application thereof to various types of regenerative medicine has been studied and also because there is a possibility that the above cell group is utilized in cultured blood business.

The surface of the cell culture diaphragm of the present invention may be modified by a hydrophilic treatment or the like, as described in the production process of a composite porous membrane and its supporting porous membrane.

A process of modifying the surface of the cell culture diaphragm is not limited. As in the case of the composite porous membrane or supporting porous membrane, the coating method is preferable. The surface modification of the cell culture diaphragm can be carried out for the purpose of suppressing cellular adhesiveness, or to the opposite, for the purpose of

imparting such cellular adhesiveness. When the coating method is applied, examples of a coating polymer used herein may include the aforementioned hydrophilic polymers such as collagen, fibronectin, vitronectin, 5 proteoglycan, or glycosaminoglycan, and conventionally known biocompatible polymers such as gelatin, lectin, or polylysine. These polymers can be used singly or in combination of two or more types.

[0056]

10 Measurement methods used in the present invention will be described below.

(1) Average pore diameter D, standard deviation of pore diameter  $\sigma_d$ , opening ratio, and the percentage of through-pores of porous membrane, honeycomb-structured 15 thin porous membrane, and etched membrane of composite porous membrane

The average pore diameter D, standard deviation of pore diameter  $\sigma_d$ , opening ratio, and the percentage of through-pores of a porous membrane can be 20 measured by taking an optical- or scanning electron- photomicrograph from the direction vertical to the membrane flat surface of the porous membrane, picking up the pore group (through-pores and non-through pores) of the porous membrane observed on the obtained planar 25 image (photograph) using image analyze software Image- Pro Plus (manufactured by Media Cybernetics, Version 4.0 for Windows (registered trade mark)), and analyzing the obtained image.

Specifically, the obtained composite porous membrane is cut from the periphery of the center into a square with a side of 6.7 cm. The center thereof is defined as point A, and the 4 angles thereof are 5 defined as B', C', D', and E'. In addition, 4 midpoints between point A and each of the above 4 angles are defined as B, C, D, and E. Thereafter, the peripheral portions of these 9 points is photographed with a scanning electron microscope (S-3000N, 10 manufactured by Hitachi Ltd.) from the direction vertical to the membrane face on the side to which the porous membrane has been adhered (1,000 to 3,000-fold).

The thus obtained 9 photographs are incorporated into image analysis software. An image 15 range including approximately 200 pores is arbitrarily selected from each photograph, and the image contrast is then fully adjusted, such that it can be analyzed. The dark region (pore region) is automatically extracted. Moreover, from among the thus extracted, 20 dark regions, those clearly differing from pore portions are manually eliminated. Thereafter, the average pore diameter of pores contained in each of the selected 9 is calculated. Subsequently, the values of 9 photographs are averaged, so as to obtain "average 25 pore diameter D."

The term "standard deviation of pore diameter  $\sigma_d$ " is used to mean a value obtained by further averaging the standard deviations of pore diameters in

the 9 image ranges, whose "average pore diameter D" has been determined as described above. The term "opening ratio" is used to mean a value that is obtained by averaging 9 values of opening ratio obtained in the 5 same above image ranges.

In each of the 9 image regions, whose D,  $\sigma_d$ , and opening ratio are calculated as described above, the total number of pores contained in each photograph is indicated with N1, and the number of through-pores 10 in the total number is indicated with N2. Both types of pores are counted, and the value obtained by the formula  $N2/N1 \times 100$  (%) is calculated. The percentage of through-pores is calculated as a mean value of the thus obtained 9 values.

15 The average pore diameter D, standard deviation of pore diameter  $\sigma_d$ , and opening ratio of a honeycomb-structured thin porous membrane, and those of an etched membrane, are measured and calculated in the same above manner. However, such a honeycomb-20 structured thin porous membrane or etched membrane does not have a supporting porous membrane. Accordingly, with regard to the honeycomb-structured thin porous membrane, through-pores are defined as pores, through which a disciform specimen holder or a tape used for 25 adhesion to the specimen holder can be observed. Thus, the ratio of such through pores is calculated. In addition, with regard to the etched membrane, since it has a high membrane thickness, it has been difficult to

observe the structure of adhesion face through pores.

Thus, from the viewpoint of production process thereof, it is assumed that pores are all through-pores.

[0057]

5 (2) Process of measuring average membrane thickness  $T$  and standard deviation of membrane thickness  $\sigma_T$  of porous membrane of composite porous membrane, honeycomb-structured thin porous membrane, and etched membrane, and observation of sectional structure

10 A composite porous membrane is gently adhered and fixed to a disciform specimen holder of a scanning electron microscope, using a two-sided tape.

Thereafter, the porous membrane is coated with platinum via evaporation. (The thickness of the membrane coated

15 via evaporation was set at approximately 12 nm.)

Thereafter, this membrane is observed under a scanning electron microscope (S-3000N, manufactured by Hitachi Ltd.), a photograph of a membrane section is then taken from the direction immediately lateral to the membrane

20 (membrane flat surface direction). Thereafter, the average membrane thickness  $T$  of a composite porous membrane and that of a porous membrane constituting it are measured from the membrane section in this photograph based on the scale described therein.

25 Specifically, the sections near the 9 points (A to E and B' to E'), which have been selected for the calculation of the average pore diameter  $D$  in (1) above, are observed under a scanning microscope, and

the membrane thickness is then calculated at intervals of 50  $\mu\text{m}$ , using the scale in the image. Such membrane thickness is measured at approximately 100 points in each of the 9 points. When 100 points cannot be observed in a scanning electron microscope sample, several samples are prepared from the periphery of the same point, so that the points to be observed can be increased. The average membrane thickness of each of the 9 points is calculated from the thus obtained membrane thickness. Subsequently, the average membrane thicknesses of the 9 points are averaged, so as to calculate an "average membrane thickness T."

The honeycomb-structured thin porous membrane and the etched membrane are also observed in the same manner.

As with a pre-treatment performed before observation under a scanning electron microscope, a sample used for cross-sectional observation is prepared by immersing in ethanol, freezing with a liquid nitrogen, and then cutting it.

(3) Measurement of average pore size of non-woven fabric

An average pore size is evaluated in accordance with the bubble point method described in ASTM-F316-86, using Automated Perm Porometer (registered trade mark) (manufactured by Porous Materials, Inc.). For the measurement, a liquid being suitable for sufficiently wetting the inside of pores

of the non-woven fabric is used.

[0058]

(4) Adhesion test

A composite porous membrane is cut into a  
5 square with a size of 10 mm × 10 mm, and this square is  
used as a test piece. This test piece is placed in a  
50-ml beaker filled with 50 ml of water, and it is  
immersed therein for 30 minutes. Thereafter, a stirrer  
bar with a length of 25 mm (maximum diameter: 8 mm) is  
10 placed therein, and the water is then stirred at a rate  
of 200 rpm for 30 minutes. Thus, it is observed  
whether or not a supporting porous membrane is removed  
from a porous membrane. A case where the supporting  
porous membrane is not removed from the porous membrane  
15 is represented by an open circle, and a case where it  
is removed therefrom is represented by a cross.

(5) Simple tensile test

A composite porous membrane, honeycomb-  
structured thin porous membrane (Comparative example 1)  
20 or an etched membrane (Comparative example 4) is cut  
into a piece with a size of 15 × 25 mm, and this piece  
is used as a test piece. The points that are 5 mm from  
both ends (short side portions) of each test piece are  
nipped with BINDER CLIPS (registered trade mark) (No.  
25 107, manufactured by LION). Thereafter, one point is  
fixed, so as to suspend the membrane in the vertical  
direction. A weight of 30 g or 50 g is attached to the  
other clip, and it is then observed whether or not the

composite porous membrane, honeycomb-structured thin porous membrane or etched membrane is broken. A case where such a membrane is not broken even with a weight of 50 g (tensile strength: 50 g or more) is evaluated 5 as an open circle, and a case where such a membrane is broken with a weight of 30 g (tensile strength: less than 30 g) is evaluated as a cross.

(6) Water permeation test

Composite porous membranes that have been 10 punched into 25 mmΦ (Examples 1 to 4), membrane sections obtained by overlaying a honeycomb-structured thin porous membrane on the supporting porous membrane (that is a coated non-woven fabric in the present example) of a composite porous membrane whose water permeability is 15 to be compared and then punching out it into a round of 25 mmΦ (Comparative examples 1 and 2), and an etched membrane (Comparative example 4) punched into a round of 25 mmΦ, are prepared. The thus prepared membranes are set into a commercially available filter holder 20 (Swin-Lok™ Filter Holder, manufactured by CORNING), so as to conduct a water permeation test. In the case of the composite porous membrane and the membrane obtained by overlaying a honeycomb-structured thin porous membrane on a supporting porous membrane, it is set 25 such that the porous membrane or honeycomb-structured thin porous membrane is disposed on the water entrance side of the filter holder.

As such a water permeation test, a 50-ml

disposable syringe (manufactured by Terumo Corp.) is connected with the aforementioned water entrance side of the filter holder, and it is vertically erected. Thereafter, a filter sample is moistened with  
5 approximately 1 ml of ethanol. Thereafter, the disposable syringe is filled with distilled water, and the time required for the distilled water to freely fall from a syringe scale of 60 ml to 30 ml is then measured, thereby calculating the amount of water  
10 permeated per filter unit area and per unit time.

[0059]

(7) Simple hemocyte suspension permeation test

A composite porous membrane or etched membrane (Comparative example 4) that has been punched  
15 into a round of 25 mmΦ is set in a commercially available filter holder (Swin-Lok™ Filter Holder, manufactured by CORNING), so as to conduct a hemocyte suspension permeation test. In the case of a composite porous membrane, it is set such that the porous  
20 membrane is disposed on the hemocyte suspension entrance side of the filter holder.

The hemocyte suspension used herein is obtained by previously removing leukocytes from fresh human whole blood using a coated non-woven fabric or  
25 the like, so as to reduce the concentration of leukocytes contained therein to 1/630.

A 10-ml disposable syringe (manufactured by Terumo Corp.) is connected with the aforementioned

hemocyte suspension entrance side of the filter holder, and it is vertically erected. Thereafter, the disposable syringe is filled with the hemocyte suspension up to the scale of 5 ml, and the time 5 required for the hemocyte suspension to freely fall from a syringe scale of 5 ml to 3 ml is then measured. The time required for permeation of 2 ml of the hemocyte suspension is evaluated.

Such "fresh human whole blood" is prepared by 10 adding, as an anticoagulant, 14 cm<sup>3</sup> of a filtrated CPD solution (a solution obtained by dissolving 26.3 g of trisodium citrate dihydrate, 3.27 g of citric acid monohydrate, 23.2 g of glucose, and 2.51 g of sodium dihydrogen phosphate dihydrate, in 1 L of distilled 15 water used for injection, and then filtrating it through a filter with a pore size of 0.2 µm) to 100 cm<sup>3</sup> of collected blood, mixing them, and conserving the mixture at 20°C for 3 hours.

[0060]

20 (8) Evaluation of capability of removing leukocytes

An integral-type filter structure as shown in Fig. 3 is evaluated.

Such capability of removing leukocytes is evaluated by passing 450 cm<sup>3</sup> of fresh human whole blood 25 through a filter device at a constant flow rate of 25 cm<sup>3</sup>/min., using a syringe pump, collecting a certain amount of blood from all the whole blood recovered before and after filtration, and measuring the

concentration of leukocytes with a residual leukocyte measurement reagent system, LeucoCOUNT™ kit, a flow cytometer FACS Calibur, and analysis software CELL Quest (all of which are manufactured by BD Bioscience,  
5 U.S.A).

The aforementioned blood filtration experiment was carried out twice. The values are obtained using the following formula (1). A mean value of such values is defined as the value of such  
10 capability of removing leukocytes.

Capability of removing leukocytes =  $-\log$  (the concentration of leukocytes after filtration of a hemocyte suspension/the concentration of leukocytes before filtration thereof) ... (1)

15 (9) Calculation of volume of filter element (V)

In the case of leukocyte removal filter devices used in Examples and Comparative examples, the supporting membrane of a composite porous membrane used as a second filter is made from the same material as  
20 that of a first filter. In addition, when compared with the first filter, the used amount of the porous membrane used of such a composite porous membrane is substantially negligible. Thus, V is calculated using the following formula (2).

25  $V = W_f[(1/d) - (1/\rho)] \dots (2)$

Herein, d ( $\text{g}/\text{cm}^3$ ) represents the filling density of the total filter element that is filled in the filter holder;  $W_f$  ( $\text{g}$ ) represents the weights of the

first and second filters filled therein; and  $\rho$  (g/cm<sup>3</sup>) represents the density of a material forming the first filter and the supporting porous membrane of the second filter (composite porous membrane). For example, when 5 the first filter and the supporting porous membrane are non-woven fabrics made from polyethylene terephthalate,  $\rho$  is approximately 1.3.

#### EXAMPLES

##### [0061]

10 The present invention will be described in detail in the following examples and comparative examples. However, these examples are not intended to limit the scope of the present invention.

##### Example 1

15 1. Production of coated non-woven fabric piece

###### 1-1. Synthesis of coating polymer

<Synthesis of 2-hydroxyethyl methacrylate (HEMA) /2-(N,N-dimethylamino)ethyl methacrylate (DMAMA) random copolymer>

20 126 g (0.970 mol) of 2-hydroxyethyl methacrylate (HEMA, manufactured by Mitsubishi Rayon Co., Ltd.), 4.72 g (0.030 mol) of 2-(N,N-dimethylamino)ethyl methacrylate (DMAMA, manufactured by Wako Pure Chemical Industries, Co., Ltd.), and 460 g 25 of ethanol were placed in a separable flask (capacity: 1 L). Thereafter, oxygen was removed by nitrogen bubbling, and the temperature of the reaction system was then increased to 60°C, while maintaining the inside

of the container in a nitrogen atmosphere. Thereafter, a deoxidized ethanol solution (ethanol: 40.0 g), in which 0.822 g (5.01 mol) of azobisisobutyronitrile (AIBN, manufactured by Wako Pure Chemical Industries, Co., Ltd.) had been dissolved, was added dropwise to the above reaction system over approximately 1 hour. The obtained mixture was continuously stirred at 60°C, and 225 minutes after initiation of the addition of AIBN, p-methoxyphenol (manufactured by Wako Pure Chemical Industries, Co., Ltd.) was added to the reaction solution, so as to terminate the polymerization reaction. Thereafter, n-hexane was added bit by bit to the obtained reaction solution, so as to precipitate a polymer. The polymer was taken out by decantation. Thereafter, dissolution in ethanol and reprecipitation operation using n-hexane were repeated several times, so as to purify the polymer.

After such purification, the yield of the polymer (with respect to the amount of the monomers added) was found to be 72 wt %. The number average molecular weight ( $M_n$ ) of the polymer obtained by GPC measurement (relative to standard polystyrene) was found to be  $1.2 \times 10^5$ , and the weight average molecular weight thereof ( $M_w$ ) was found to be  $4.1 \times 10^5$ . Thus,  $M_w/M_n$  was found to be 3.4. In addition, the copolymerization composition ratio in the polymer, which was calculated based on the measurement of the amount of monomer residue by gas chromatography (GC)

performed on the reaction solution after completion of the polymerization, was found to be HEMA/DMAMA = 97/3 (molar ratio).

1-2. Coating of non-woven fabric with coating polymer  
5 (HEMA/DMAMA (97/3 (molar ratio)) copolymer)

An ethanol solution containing 1.0 wt % of the HEMA/DMAMA (97/3 molar ratio) copolymer obtained in 1-1. above was prepared. The thus prepared solution was used as a coating solution. A polyethylene 10 terephthalate non-woven fabric (manufactured by Asahi Kasei Corp.; Microweb) having an average fiber diameter of 1.2  $\mu\text{m}$ , an average pore size of 6.3  $\mu\text{m}$ , and a mass per unit area of 40g/m<sup>2</sup> (fiber weight for 1 m<sup>2</sup> of non-woven fabric), and a thickness of 0.2 mm, was selected 15 as a non-woven fabric to be used herein. This non-woven fabric was continuously immersed in a coating solution for an immersion time of 5 seconds. Thereafter, the non-woven fabric was nipped with a nip roll and passed through it, so as to remove an excess 20 coating solution. Thereafter, the resultant was dried, so as to obtain a coated non-woven fabric.

2. Production of composite porous membrane

Using chloroform as a solvent, there was prepared a 1g/L hydrophobic organic solvent solution 25 containing, as solutes, poly- $\epsilon$ -caprolactone (PCL) (manufactured by Wako Pure Chemical Industries, Co., Ltd.; average molecular weight: 70,000 to 100,000) and a polyacrylamide amphipathic polymer (represented by

the aforementioned structural formula (1)). The weight ratio of PCL/polyacrylamide amphipathic polymer was 9/1.

The polyacrylamide amphipathic polymer  
5 represented by the chemical formula (1) was a random copolymer, wherein the molar ratio between unit m and unit n was m/n = 4/1.

The polyacrylamide amphipathic polymer was produced by subjecting dodecyl acryloyl amide ( $\text{CH}_2 = \text{CH}-\text{CONH-C}_{11}\text{H}_{22}-\text{CH}_3$ ) (A mole) and 6-acrylamide hexanoic acid ( $\text{CH}_2 = \text{CH-CONH-C}_5\text{H}_{10}-\text{COOH}$ ) (B mole) at a molar ratio of A/B = 4/1 to a radical polymerization method using AIBN as an initiator in benzene (monomer concentration: 6 wt %; polymerization temperature: 60°C). The weight  
15 average molecular weight  $M_w$  of the obtained amphipathic polymer was found to be  $2.5 \times 10^4$  (GPC method; relative to standard polystyrene).

6-acrylamide hexanoic acid was synthesized by subjecting acryloyl chloride (manufactured by Aldrich)  
20 and 6-aminohexanoic acid (manufactured by Aldrich) to a dehydrochlorination reaction at 0°C in an aqueous solvent. Dodecyl acryloyl amide was synthesized by subjecting acryloyl chloride and dodecylamine (manufactured by Aldrich) to a dehydrochlorination  
25 reaction at 0°C in a chloroform solvent.

Subsequently, a coated non-woven fabric piece prepared in 1-2. above was cut into a square with a side of 16 cm. Thereafter, the non-woven fabric was

immersed in pure water in a beaker, and deaeration was then carried out using an ultrasonic cleaner for 5 minutes, so that the non-woven fabric was allowed to sufficiently retain water. The thus obtained non-woven  
5 fabric retaining a sufficient amount of water (hydrous non-woven fabric) was removed from the beaker and then placed on a glass plate. Thereafter, a metal frame with a thickness of 1 mm that had been punched into a square with a side of 15 cm was disposed on the non-  
10 woven fabric, such that the hydrous non-woven fabric was exposed from the whole area of the punched portion of the metal frame. Thus, the glass plate, the hydrous non-woven fabric, and the metal frame were laminated, and the resultant was fixed with a clip.

15 Thereafter, 14 cm<sup>3</sup> of the prepared chloroform solution containing PCL and a polyacrylamide amphipathic polymer was gently poured into the punched portion of the metal frame, from which the hydrous non-woven fabric was exposed. Thereafter, air with a  
20 relative humidity of 60% was blown at an amount of 6 L/min to the surface of the above solution in a thermo-hygrostat with a room temperature of 25°C and a relative humidity of 40%, so as to remove chloroform, thereby forming a porous membrane containing PCL as a main  
25 component on the hydrous non-woven fabric.

Subsequently, the metal frame was removed, and the non-woven fabric was subjected to air drying at room temperature, so as to obtain a composite porous

membrane. The obtained composite porous membrane had a membrane thickness of approximately 240  $\mu\text{m}$ . The opening ratio, D,  $\sigma d/D$ , the percentage of through-pores, T, and  $\sigma t/T$  are as shown in Table 1.

5           The scanning electron photomicrographs obtained by photographing the surface of the obtained composite porous membrane from the porous membrane side are shown in Fig. 1 (1,000-fold) and Fig. 2 (3,000-fold). The structure of the non-woven fabric that is a supporting porous membrane could be observed through pores of the porous membrane. In addition, a state where fibers constituting the non-woven fabric penetrated into the porous membrane and where as a result, pores are partially occluded therewith, could 10 also be observed on the surface of the porous membrane.

15           Moreover, a scanning electron photomicrograph showing the section of the composite porous membrane is shown in Fig. 3 (3,000-fold). It could be observed that each pore had a structure as a spherical through-pore which swelled in the porous membrane, and that pores adjacent to one another were communicated with 20 one another.

An adhesion test was carried out. As a result, it was found that the porous membrane was not separated from the supporting porous membrane.

25           In addition, a simple tensile test was also carried out. As a result, it was found that a test piece was not broken with a force of 50 g. No cracks

were observed on the porous membrane.

A water permeation test was carried out using pure water. The result was found to be 17.6 ml/cm<sup>2</sup>/min.

The obtained composite porous membrane was  
5 immersed in a solution containing 0.1 wt % of the HEMA/DMAMA (97/3 (molar ratio)) copolymer synthesized in 1-1. above (solvent: ethanol) for 10 seconds for coating. After completion of the immersion, the membrane was fully dried, so as to obtain a coated  
10 composite porous membrane.

The coated composite porous membrane was subjected to a simple permeation test using a hemocyte suspension. As a result, the period of time required for permeation of 2 ml of the hemocyte suspension was  
15 found to be 30 seconds. When compared with the result obtained in Comparative example 4 described later, this was a good permeation rate.

[0062]

Example 2

20 A composite porous membrane was produced in the same manner as in the section 2 of Example 1 with the exception that dichloromethane was used instead of chloroform as a solvent for the used hydrophobic organic solvent solution.

25 The opening ratio, D,  $\sigma d/D$ , the percentage of through-pores, T, and  $\sigma t/T$  of the porous membrane of the obtained composite porous membrane are as shown in Table 1.

An adhesion test was carried out. As a result, it was found that the porous membrane was not separated from the supporting porous membrane.

A simple tensile test was also carried out.

5 As a result, it was found that a test piece was not broken with a force of 50 g. In addition, no cracks were observed on the porous membrane.

A water permeation test was carried out using pure water. The result was found to be 15.4 ml/cm<sup>2</sup>/min.

10 [0063]

Example 3

A composite porous membrane was produced in the same manner as in the section 2 of Example 1 with the exception that polysulfone (PSU: manufactured by 15 Teijin Acomo Engineering Plastics, UDEL P-3500) was used instead of PCL as a solute for the used hydrophobic organic solvent solution.

The opening ratio, D, σd/D, the percentage of through-pores, T, and σt/T of the porous membrane of 20 the obtained composite porous membrane are as shown in Table 1.

An adhesion test was carried out. As a result, it was found that the porous membrane was not separated from the supporting porous membrane.

25 A simple tensile test was also carried out. As a result, it was found that a test piece was not broken with a force of 50 g. In addition, no cracks were observed on the porous membrane.

A water permeation test was carried out using pure water. The result was found to be 14.2 ml/cm<sup>2</sup>/min.  
[0064]

Example 4

5 A composite porous membrane was produced in the same manner as in the section 2 of Example 1 with the exceptions that PSU was used instead of PCL as a solute for the used hydrophobic organic solvent solution, that a polymer (concentration: 4 g/L; liquid  
10 amount: 21 cm<sup>3</sup>) was casted, and that chloroform was removed in a thermo-hygrostat with a room temperature of 28°C and a relative humidity of 43%.

The opening ratio, D, σd/D, the percentage of through-pores, T, and σt/T of the porous membrane of  
15 the obtained composite porous membrane are as shown in Table 1.

An adhesion test was carried out. As a result, it was found that the porous membrane was not separated from the supporting porous membrane.

20 A simple tensile test was also carried out. As a result, it was found that a test piece was not broken with a force of 50 g. In addition, no cracks were observed on the porous membrane.

A water permeation test was carried out using  
25 pure water. The result was found to be 19.6 ml/cm<sup>2</sup>/min.  
[0065]

Comparative example 1

A honeycomb-structured thin porous membrane

was formed in the same manner as in section 2 of Example 1 with the exception that 11 cm<sup>3</sup> of a hydrophobic organic solvent solution was directly poured into a round glass Petri dish with a diameter of 5 15 cm without using a coated non-woven fabric. A thin porous membrane formed on the Petri dish was peeled by addition of ethanol. Thereafter, it was attached to and fixed on a ring-shaped supporting frame, and it was then removed.

10 The opening ratio, D,  $\sigma_d/D$ , the percentage of through-pores, T, and  $\sigma_t/T$  of the obtained honeycomb-structured thin porous membrane are as shown in Table 1.

15 A water permeation test was carried out using pure water. The result was found to be 18.9 ml/cm<sup>2</sup>/min.

In addition, a simple tensile test was also carried out. As a result, it was found that a test piece was broken only with a force of 30 g. Thus, it was revealed that this membrane did not have practical 20 strength.

[0066]

Comparative example 2

A honeycomb-structured thin porous membrane was produced in the same manner as in Example 4 with 25 the exception that 11 cm<sup>3</sup> of a hydrophobic organic solvent solution was directly poured into a round glass Petri dish with a diameter of 15 cm without using a coated non-woven fabric.

The opening ratio, D,  $\sigma d/D$ , the percentage of through-pores, T, and  $\sigma t/T$  of the obtained honeycomb-structured thin porous membrane are as shown in Table 1.

5 A water permeation test was carried out using pure water. The result was found to be 20.1 ml/cm<sup>2</sup>/min.

In addition, a simple tensile test was also carried out. As a result, it was found that a test piece was broken only with a force of 30 g. Thus, it  
10 was revealed that this membrane did not have practical strength.

[0067]

Comparative example 3

A composite porous membrane was produced in  
15 the same manner as in Example 4 with the exception that 17 ml of a hydrophobic organic solvent solution was casted in a dry state without impregnating the coated non-woven fabric with water.

A scanning electron photomicrograph of the  
20 obtained composite porous membrane showed that cast solution-derived PSU penetrated into the supporting membrane and that several pores of the supporting membrane were thereby occluded. In addition, several honeycomb-state pores were observed on the PSU portion  
25 on the side to which air was blown on the composite porous membrane. However, in a majority of pores, the non-woven fabric was exposed, or pores were broken or clogged. Thus, differing from Examples 1 to 4, a

smooth porous membrane with high pore size uniformity was not found. Accordingly, it was difficult to determine the opening ratio, D,  $\sigma d/D$ , the percentage of through-pores, T, and  $\sigma t/T$  of the obtained composite  
5 porous membrane.

[0068]

Comparative example 4

A pure water permeation test was carried out using an etched membrane made from polycarbonate (PC)  
10 (manufactured by MILLIPORE; Isopore Membrane Filter). The result was found to be 12.0 ml/cm<sup>2</sup>/min.

In addition, the etched membrane was coated with a HEMA/DMAMA (97/3 (molar ratio)) copolymer in the same manner as in Example 1, and a simple hemocyte  
15 suspension permeation test was carried out. The result was found to be 57 seconds.

A simple tensile test was also carried out. As a result, it was found that a test piece was not broken with a force of 50 g. Moreover, no cracks were  
20 observed.

The opening ratio, D,  $\sigma d/D$ , the percentage of through-pores, T, and  $\sigma t/T$  of this etched membrane made from PC are as shown in Table 1. Since this membrane had a high thickness, the percentage of through-pores  
25 could not be confirmed by observation from the membrane flat surface. However, taking into consideration its production method, it was assumed to be almost 100%. Furthermore, the shape of a pore on the membrane

section was cylindrical.

[0069]

Example 5

1. Production of leukocyte removal device

5 1-1. Evaluation of capability of first filter of  
removing leukocytes

Sixteen slices of square non-woven fabrics were cut out of the coated non-woven fabric piece produced in the process described in the section 1-2 of Example 1, such that the effective area of a filter could be  $45 \text{ cm}^2$  when it was filled in a filter holder. (The effective size of the filter was  $6.7 \text{ cm} \times 6.7 \text{ cm}$ .) The thus obtained sixteen slices were filled in a filter holder, resulting in a filling density of  $0.23 \text{ g/cm}^3$ . Thereafter, a filtration experiment was carried out twice, and  $450 \text{ cm}^3$  of fresh human whole blood was passed through this filter. As a result, the mean value of the capability of the first filter of removing leukocytes was found to be 2.8.

20 1-2. Production of integral-type leukocyte removal filter device and evaluation of capability thereof of removing leukocytes

Sixteen slices of square samples were cut out of any given positions of the coated non-woven fabric piece produced in the section 1-2 of Example 1, such that the effective filter size could be  $6.7 \text{ cm} \times 6.7 \text{ cm}$ . (The effective filter area was  $45 \text{ cm}^2$ .) Such sixteen slices were laminated, so as to produce a first

filter.

Subsequently, a single slice of square sample of the same size as that of the first filter was cut out of the center of the coated composite porous membrane obtained in section 2 of Example 1, and this was used as a second filter. (The effective area of the second filter was  $45 \text{ cm}^2$ .) The first filter was overlaid on the second filter, and the thus overlaid filters were filled into a filter holder, such that the entire filter element had a filling density of  $0.23 \text{ g/cm}^3$ , thereby constituting an integral-type leukocyte removal filter device. The first filter was disposed on the entrance side of a hemocyte suspension to be treated, and the second filter was disposed on the exit side of the treated blood.

Such a filling density of  $0.23 \text{ g/cm}^3$  was considered to be the same as those of the supporting membranes of the first and second filters. Defining  $W_f$  as the weight of 17 slices of square non-woven fabrics, the aforementioned formula (2) was used for calculation. As a result, volume of filter element  $V$  was found to be  $12 \text{ cm}^3$ .

Thereafter,  $450 \text{ cm}^3$  of fresh human whole blood was passed through this integral-type leukocyte removal filter device, so as to measure the capability of the device of removing leukocytes. A blood filtration experiment was carried out twice. As a result, the mean value of the capability of removing leukocytes was

found to be 4.3.

The above results are shown in Table 2. When compared with Comparative example 5 described later, although almost the same value was maintained as capability of removing leukocytes, the volume of a filter element was significantly reduced. Thus, it was found that a leukocyte removal filter device capable of significantly reducing the loss of a hemocyte suspension could be obtained.

10 [0070]

Example 6

A leukocyte removal filter device was produced in the same manner as in Example 6 with the exceptions that two slices of the coated composite porous membranes obtained in section 2 of Example 1 were used as a second filter, and that fifteen slices of the coated non-woven fabrics produced in section 1-2 of Example 1 were used as a first filter.

In this case also, the filling density of the entire filter element was  $0.23 \text{ g/cm}^3$ . Thus, the volume of the filter element was  $12 \text{ cm}^3$  (the first filter + two slices of supporting membranes).

Thereafter,  $450 \text{ cm}^3$  of fresh human whole blood was passed through this integral-type leukocyte removal filter device, so as to measure the capability of removing leukocytes thereof. A blood filtration experiment was carried out twice. As a result the mean value of the capability of removing leukocytes was

found to be 4.5.

These results are shown in Table 2.

[0071]

Example 7

5           The composite porous membrane obtained in Example 2 was immersed in a solution containing 0.1 wt % of a HEMA/DMAMA (97/3 (molar ratio)) copolymer (solvent: ethanol) for 10 seconds, and it was then removed therefrom, followed by drying. Thus, the  
10 composite porous membrane was coated with the above solution, and it was defined as a coated composite porous membrane. Thereafter, a leukocyte removal filter device was produced in the same manner as in Example 6 with the exception that a slice of the above  
15 coated composite porous membrane was used as a second filter.

In this case also, the filling density of the entire filter element was 0.23 g/cm<sup>3</sup>. Thus, the volume of the filter element was 12 cm<sup>3</sup> (the first filter + two  
20 slices of supporting membranes).

Thereafter, 450 cm<sup>3</sup> of fresh human whole blood was passed through this integral-type leukocyte removal filter device, so as to measure the capability of removing leukocytes thereof. A blood filtration  
25 experiment was carried out twice. As a result the mean value of the capability of removing leukocytes was found to be 4.5.

These results are shown in Table 2.

[0072]

Comparative example 5

32 slices of square non-woven fabric samples were cut out of the non-woven fabric coated with a 5 HEMA/DMAMA (97/3 (molar ratio)) copolymer obtained in section 1-2 of Example 1, such that the effective filter area could be 45 cm<sup>2</sup> (effective filter size: 6.7 cm × 6.7 cm). Such 32 slices were filled into a filter holder, so as to constitute a leukocyte removal filter 10 device (filling density: 0.23 g/cm<sup>3</sup>). A composite porous membrane (that is, a second filter) was not used herein. The volume of a filter element was 24 cm<sup>3</sup>, and the effective filter area was 45 cm<sup>2</sup>.

Thereafter, a leukocyte filtration experiment 15 was carried out twice. That is, 450 cm<sup>3</sup> of fresh human whole blood was passed through this leukocyte removal filter device twice. As a result, the mean value of the capability of removing leukocytes was found to be 4.2.

20 The results are shown in Table 2. This device exhibited high capability of removing leukocytes, but the volume of a filter element was twice larger than that of Example 5.

[0073]

25 Comparative example 6

An integral-type leukocyte removal device was produced in the same manner as in Example 5 with the exceptions that a first filter was constituted with 3

slices of coated non-woven fabrics and that a second filter was constituted with 2 slices of coated composite porous membranes.

The capability of the first filter of  
5 removing leukocytes was 0.5. The volume of filter element (the first filter + the supporting membrane of the composite porous membrane) of the finally constructed integral-type leukocyte removal filter device was 2 cm<sup>3</sup>.

10 Thereafter, in order to measure the capability of this integral-type leukocyte removal filter device of removing leukocytes, 450 cm<sup>3</sup> of fresh human whole blood was passed through the above device. However, since the filter was occluded due to clogging  
15 during the filtration, such evaluation ended up unsuccessfully.

It was found that when the capability of the first filter of removing leukocytes was insufficient, the clogging of the filter occurs unfavorably.

20 [0074]

Example 8

1. Production of cup-type culture apparatus by processing of composite porous membrane

The composite porous membrane produced in  
25 Example 3 was cut into a round shape of 13 mmφ. Using a chloroform solution containing PSU with a polymer concentration of 17% as an adhesive agent, the porous membrane face of the cut round composite porous

membrane was attached to one end face of a glass ring (manufactured by Asahi Technoglass Corp.; Cloning Ring; inside diameter: 10 mm, outside diameter: 12 mm, and height: 10 mm), so as to produce a cup-type culture apparatus. This cup-type culture apparatus was subjected to air drying and then to vacuum drying. The resultant culture apparatus was treated with an autoclave at 121°C for 10 minutes, so as to sterilize it.

The thus autoclave-treated cup-type culture apparatus was immersed in an aqueous 0.3% type I collagen solution (CELLGENI-PC, manufactured by Koken Co., Ltd.), followed by air drying, thereby obtaining a collagen-coated cup-type culture apparatus.

## 15 2. Cell culture

### 2-1. Introduction of cells into supporting porous membrane

Using a different diameter adaptor, one end of a silicon tube with an inside diameter of 12 mm and an outside diameter of 14 mm was connected with an opening of a 10-ml disposable syringe (manufactured by Terumo Corp). The other end thereof was connected with a glass ring portion of the cup-type culture apparatus coated with collagen in the aforementioned section 1.

Human cervical adenocarcinoma cells (ATCC No. CCL-2) were used as model cells. Such cells were added to a cell culture solution (D-MEM, manufactured by GIBCO), resulting in  $1 \times 10^4$  cells/100  $\mu\text{L}$ , so as to

prepare a cell suspension.

The cup-type culture apparatus was placed with the supporting porous membrane of a composite porous membrane located upward, and 100 µL of the  
5 prepared cell suspension was then added dropwise to the supporting porous membrane, followed by aspiration with the disposable syringe. Thereafter, 5 ml of a culture solution was further added dropwise thereto, followed by aspiration, so as to introduce cells. In a state  
10 where the supporting porous membrane was located upward, the resultant was left under aseptic conditions for 30 minutes. The number of cells contained in the recovered cell culture solution that had been passed through the composite porous membrane and then poured  
15 into the syringe was intended to be counted under a phase-contrast optical microscope using a hemacytometer (EOSINOPHIL COUNTER, manufactured by Sun Lead Glass). However, the presence of cells could not be confirmed.

## 2-2. Cell culture

20 Thirty minutes later, while maintaining the state where the supporting porous membrane was located upward, it was placed in a well of a 24-well polystyrene culture plate (Multiwell™ Cell Culture Plate, manufactured by BD Bioscience, U.S.A.).  
25 Thereafter, 2 ml of a culture solution was added thereto, such that even the upper portion of the membrane was immersed in the culture solution. This culture plate was left at rest in a moisture-retentive

incubator at 37°C in the presence of 5% CO<sub>2</sub> in an atmosphere of 95% air, and it was cultured for 2 days.

Two days later, the cup-type culture apparatus was removed, and 5 ml of a 0.05% trypsin 5 solution was passed through it. Thereafter, 10 ml of a culture solution was further passed through it, and cells in the supporting porous membrane were then recovered. The number of cells in the recovered 10 solution was counted under a phase-contrast optical microscope using a hemacytometer. As a result, it was found that the number of cells 3-times increased.

Likewise, after completion of the culture, the cup-type culture apparatus was removed from the well, and the cells were then fixed with an aqueous 2% 15 glutaraldehyde solution. Thereafter, the composite porous membrane was cut out of the cup-type culture apparatus.

The section of the cut composite porous membrane was observed under a scanning electron 20 microscope, so as to examine the distribution of cells in the supporting porous membrane. As a result, it was found that the cells were present on the periphery of the porous membrane, and that the cells were also present in other portions of the supporting porous 25 membrane.

Moreover, when compared with comparative example 7, the number of grown cells was large. It was found that since the area acting as a scaffolding for

cells increased due to the presence of the supporting porous membrane, the cells could efficiently be cultured.

From these results, it was found that it is  
5 possible to introduce cells into the supporting porous membrane up to the periphery of the porous membrane, and that the cells is able to grow in the supporting porous membrane. That is to say, if difference types of cells are inoculated on the porous membrane in the  
10 aforementioned state, the different types of cells are allowed to efficiently come into contact with each other through the porous membrane. Moreover, it is anticipated that the cells introduced into the supporting porous membrane up to the periphery of the  
15 porous membrane can be cultured without a decrease in the cell activity, because of interaction with other cells in the supporting porous membrane.

[0075]

Comparative example 7

20 Using an etched membrane made from polycarbonate (PC) (Isopore Membrane Filter, manufactured by MILLIPORE), a cup-type culture apparatus was produced in the same manner as in the section 1 of Example 8. The culture apparatus was  
25 sterilized and then subjected to collagen coating.

Human cervical adenocarcinoma cells (ATCC No. CCL-2) were used as model cells. Such cells were added to a cell culture solution (D-MEM, manufactured by

GIBCO), resulting in  $1 \times 10^4$  cells/100  $\mu\text{L}$ , so as to prepare a cell suspension. The cup-type culture apparatus was placed with the etched membrane side located upward, and 100  $\mu\text{L}$  of the prepared cell suspension was then added dropwise to the etched membrane, and the cup-type culture apparatus was left for 30 minutes under antiseptic conditions in the state where the etched membrane was located upward. During such a process, the culture solution was likely to pass through the etched membrane and be then poured into the cup, and the membrane face was thereby easily be dried. Thus, a lid was put thereon, so as to prevent drying. Moreover, a small amount of culture solution should be added as necessary, thereby causing extremely poor operability.

Thereafter, culture was carried out for 2 days in the same manner as in the section 2-2 of Example 8, and cells were then recovered using a trypsin solution. Thereafter, the number of the cells was counted. As a result, the number of the cells 2-times increased.

[0076]

Example 9

Human cervical adenocarcinoma cells were introduced into the collagen coated cup-type culture apparatus produced in the same manner as in the section 1 of Example 8, at an amount of  $1 \times 10^4$  cells/100  $\mu\text{l}$  in the same manner as in section 2-1 of Example 8.

Thirty minutes after the introduction, the cup-type culture apparatus was placed in a well of a 24-well polystyrene culture plate, with the supporting porous membrane located downward. Thereafter, 1 ml of 5 a culture solution was added thereto, and culture was then carried out in an incubator for 2 days.

Two days later, cells were then recovered using a trypsin solution in the same manner as in Example 8. Thereafter, the number of the cells was 10 counted. As a result, it was found that the number of the cells 2.8-times increased.

When compared with Comparative example 8, even when the cup-type culture apparatus was turned over, since the supporting porous membrane acted as a 15 scaffolding for cells, the cells were not easily removed, but they were retained in the composite porous membrane. Thus, the number of the recovered cells was large. From such results, it was found that it is extremely easy to continuously inoculate the second 20 cells on the porous membrane.

[0077]

Comparative example 8

Using an etched membrane made from polycarbonate (PC) (Isopore Membrane Filter, 25 manufactured by MILLIPORE), a collagen-coated cup-type culture apparatus was produced in the same manner as in Comparative example 7. Thereafter, the etched membrane side was disposed upward, and 100 µl of a cell

suspension containing human cervical adenocarcinoma cells at an amount of  $1 \times 10^4$  cells/100  $\mu\text{l}$  was then added dropwise on the etched membrane. Thereafter, the cup-type culture apparatus was left for 30 minutes 5 under antiseptic conditions in the state where the etched membrane was located upward, while paying attention to prevent the membrane from being dried.

Thirty minutes after addition of the cell suspension, the cup-type culture apparatus was placed 10 in a well of a 24-well polystyrene culture plate, with the etched membrane portion located downward. Thereafter, 1 ml of a culture solution was added thereto, and culture was then carried out in an incubator for 2 days.

15 Two days later, cells adhering to the etched membrane were then recovered using a trypsin solution in the same manner as in Example 8, and the number of the cells was then counted. As a result, it was found that the number of the cells decreased to 0.5-times. 20 It was considered that when the etched membrane was placed in a well, many cells were removed.

[Table 1]

## INDUSTRIAL APPLICABILITY

[0078]

The composite porous membrane of the present invention has a pore size of  $\mu\text{m}$  order, high uniformity, 5 and high opening ratio. In addition, the present composite porous membrane adopts a structure whereby the inside of the membrane has high filtration efficiency, and a supporting membrane thereof has sufficient mechanical strength. Accordingly, the 10 composite porous membrane of the present invention can be widely used as a main filter, pre-filter, or final filter for filtration (separation and recovery) of target substances of  $\mu\text{m}$  order, such as various types of cells, bacteria or yeasts, and further for the purpose 15 that requires precise size separation of  $\mu\text{m}$  order.

Specifically, the present composite porous membrane can be effectively used as a cell separation filter for batch processing or circle processing in a bioprocess field for producing value-added 20 pharmaceutical products, food products, nutrient preparations, and others.

In a medical field, the composite porous membrane of the present invention can be used as a leukocyte removal filter for whole blood, an 25 erythrocyte product, a thrombocyte product, a plasma product, etc. It may be used either singly or with the combination of the conventional filter element.

When the present composite porous membrane is

used singly, since it has high strength, it can be used as a thin-type leukocyte removal filter having no risks of membrane break due to high filtration pressure.

The present composite porous membrane can be  
5 used as a cell separation filter for various types of blood cells, such as separation of erythrocytes, leukocytes, or thrombocytes. Moreover, it can also be used as a plasma separation filter from whole blood.

According to the present invention, when  
10 leukocytes are removed, the volume of a filter element can be significantly reduced while maintaining high capability of removing leukocytes. Thus, it becomes possible to significantly reduce the loss of a hemocyte suspension (whole blood, an erythrocyte product, a  
15 thrombocyte product, a plasma product, etc.) caused by the volume of filter element during filtration. As a result, the present invention brings on various effects such that cost performance regarding blood products can be significantly improved in medical sites, that the  
20 cost generated on the filter production side can be reduced due to reduction in the amount of a filter constitutional material, and that such a thin-type product enables the efficiency of storage space or the improvement of the workability of users in medical  
25 sites.

When an electrolyte solution, an agent, or a nutrient preparation is intravenously administered in a parenteral manner, the composite porous membrane of the

present invention can also be used as an IV filter for removing foreign matters mixed (bacteria or microparticle substances), a leukocytic cell-recovering filter for recovering leukocytic cells from a 5 hematopoietic stem cell source such as peripheral blood, cord blood or bone marrow, a monocyte-recovering filter, a hematopoietic stem cell-recovering filter, or a cell separation filter used in the regenerative medicine field of various organs.

10       The cell culture diaphragm of the present invention is effectively used as a cell culture diaphragm, when the growth of useful cells of interest is controlled by intracellular contact with different cells (for example, when the cells of interest are 15 allowed to grow while suppressing its differentiation), and also when only such useful cells intend to be selectively recovered after the growth. In particular, since there is a possibility that undifferentiated hematopoietic stem cells are allowed to grow in high 20 volume using this cell culture diaphragm, it is anticipated that the present cell culture diaphragm be extremely effectively used in a regenerative medicine field or transfusion field (clean transfusion using cultured blood cells). Moreover, it is also 25 anticipated that the present cell culture diaphragm be used also in a regenerative medicine/cell therapy field involving the growth of organ-specific stem cells.

Furthermore, the composite porous membrane of

the present invention can be used as a uniformly dispersed medium for ink or the like in an electronic material field such as a master in silk-screen printing.
